Abstract

We argue that a description of supersymmetric extended objects from a unified geometric point of view requires an enlargement of superspace. To this aim we study in a systematic way how superspace groups and algebras arise from Grassmann spinors when these are assumed to be the only primary entities. In the process, we recover generalized space-time superalgebras and extensions of supersymmetry found earlier. The enlargement of ordinary superspace with new parameters gives rise to extended superspace groups, on which manifestly supersymmetric actions may be constructed for various types of \(p\)-branes, including D-branes (given by Chevalley-Eilenberg cocycles) with their Born-Infeld fields. This results in a field/extended superspace democracy for superbranes: all brane fields appear as pull-backs from a suitable target superspace. Our approach also clarifies some facts concerning the origin of the central charges for the different \(p\)-branes. © 2000 Elsevier Science B.V. All rights reserved.

1. Introduction

As is well known, the existence of consistent classical actions for extended supersymmetric objects of spatial dimension \(p\) is restricted to certain dimensions \(D\) of space-time. This is, e.g., the case of the \(p\)-branes of the minimal or ‘old’ branescan 1, which restricts the actions to certain values \((D, p)\) for which there exists a Wess–Zumino WZ term. This is needed for the \(k\)-symmetry of the full action that matches the physical bosonic and fermionic degrees of freedom on the world-volume \(W\), and the WZ term is given by a closed \((p + 2)\)-form which can be interpreted [2] as a Chevalley–Eilenberg \(3\) (CE) \((p + 2)\)-cocycle on superspace. The first classification of \(p\)-branes [1] was restricted to fields forming a scalar supermultiplet on \(W\), consisting of scalars and
spinors after gauging the $\kappa$-symmetry. The restriction to superspace coordinates $x^a, \theta^a$ on $W$ was later removed with the addition of higher spin fields, vectors or antisymmetric tensors, forming vector or antisymmetric tensor supermultiplets on $W$. This, together with the Bose-Fermi matching conditions led to an enlargement of the possibilities (see Refs. [4,5] and earlier references therein) for the classically allowed supermembranes. Recently, $p$-branes including an abelian vector gauge field on $W$ have been interpreted as (Dirichlet) $D$-branes [6] (see Ref. [7] for a review). Their kinetic term is described by a Born–Infeld type Lagrangian which replaces the usual Nambu–Goto one to accommodate the vector potential; in similarity with the $p$-branes in [1], there also exists a $\kappa$-symmetric world-volume action [8] for them. The introduction of other objects such as $L$-branes (which have linear supermultiplets on $W$) [9] etc., have enlarged the number and types of $p$-branes. Finally, the emergence of a web of dualities among the five consistent ten-dimensional string theories, all presumably subsumed, together with $D = 11$ supergravity, in the eleven-dimensional M-theory (see, e.g., Ref. [10]) has led to the ‘second superstring revolution’ and to a change of the conventional views of supersymmetry. One version of the M-theory, M-atrix theory [11], even reinterprets space-time coordinates as non-commuting matrices.

The existence of various extended objects for which there is no unified description suggests that, in the same way as Minkowski space was enlarged to the superspace $\Sigma$ to treat bosons and fermions simultaneously, it may be necessary to extend $\Sigma$ further to accommodate from a unified point of view a number of the physical aspects mentioned above. In particular, one might hope to remove the need for defining fields directly on $W$ if an extended superspace $\tilde{\Sigma}$ is introduced, as will be seen to be the case. This extension of $\Sigma$ is tantamount to enlarging the $D$-dimensional superPoincaré $\tilde{sP}$ to $\tilde{\tilde{sP}}$ and to defining the extended superspace $\tilde{\Sigma}$ by the quotient $\tilde{\tilde{sP}}/Spin(1,D – 1)$. Endowing $\tilde{\Sigma}$ with a supergroup structure means that there must exist new superalgebras going beyond the ordinary supersymmetry algebra, and several of them have been discussed in various contexts [12–22]. Our point of view, however, will be to assume that fermions (in the form of odd abelian spinor translations) are the only basic (i.e. initial) entities. We shall then look for the most general superspace groups that are allowed by group extension theory and discuss their consequences for a unified picture of superbranes. We find this path rather natural, but it is not the only one. Another possibility is to take the world-volume supersymmetry of the $p$-branes into account by elevating the target superspace coordinates to world-volume superfields [23,24] (see also Ref. [9] and references therein), but we shall not follow this superembedding or ‘double supersymmetry’ approach.

As stated above, the problem is first a mathematical one. In much the same way as rigid superspace is itself a group extension, and hence supersymmetry is the result of the non-trivial cohomology of a certain odd supertranslation group $sTr_0$ [25,26], it is worth looking for all the possible group extensions of the various $sTr_0$ (i.e. $sTr_0 = \{N = 1, sTr_{11}, sTr_{10}, IIA, IIB, etc.\}$) to explore their rôle in more general theories. At the algebra level, the possible supersymmetry algebras were already investigated in [27] and, allowing tensor ‘central’ charges, in [28] (tensorial charges were also considered in [29–31]). But there is also a physical reason behind the mathematical extension problem. It is known that the quasi-invariance of a Lagrangian under a symmetry indicates that the (second) cohomology group is non-trivial, and that the symmetry group may hence
be extended.\(^1\) This was exploited in [12] to extend the supersymmetry algebra for the supersymmetric extended objects by topological charges. For Lagrangians containing a quasi-invariant piece \(\phi^* (b)\) constructed from a form \(b\) on a group \(\Sigma\) by pulling it back to a manifold \(W\) by \(\phi^*\), where \(\phi: W \rightarrow \Sigma\), the extension may allow us, as is the case with the WZ terms \(b\) of supersymmetric objects, to obtain manifestly invariant terms \(\tilde{b}\) by defining them on an extended group manifold \(\tilde{\Sigma}\). In fact, it was shown in [16] that to every free differential algebra in \([2]\) corresponds a new space-time superalgebra, from which invariant forms can be found to define new WZ terms\(^3\). We shall take the analysis of Refs. [2,16,19] further (see also Ref. [18]) by considering various superbrane types and by emphasizing the supergroup manifold point of view. Thus, we shall look for and introduce extended superspace groups \(\tilde{\Sigma}\) in a systematic way (we restrict our attention here to rigid superspaces). The additional variables in these will determine symmetries to which topological charges may correspond via the standard Noether theorem. For the branes of the old branescans, these new variables will appear only in the WZ term and as a total differential. This will be different for the D-branes, for which we will obtain, nevertheless, that it is also possible to find an action defined on an extended superspace (thus removing the necessity of introducing directly world-volume fields) with a WZ term given by a CE \((p + 2)\)-cocycle. By showing that all these structures and extended superspaces \(\tilde{\Sigma}\) follow from a basic odd translation group \(sTr\) defined by the Grassmann spinors of the specific theory, we may conclude that the \(\tilde{\Sigma}\)’s (and the corresponding extended superPoincaré groups \(\tilde{sP}\)) are in a way as fundamental as the standard one, and necessary for a proper description of the physics involved around M-theory and its six weak coupling limit corners. The new variables may be relevant in the search for superbrane actions, in the description of dualities or in the quantisation process.

This paper is organised as follows. Section 2 contains all central extensions of \(sTr\), including ordinary superspace, for various dimensions, and its results are summarised in a table. Section 3 considers in general the inclusion of additional non-central generators. Section 4 is devoted to the structure of the new superspaces \(\tilde{\Sigma}\) and provides a compact expression for the contribution to the Noether charges coming from the WZ terms of the various possible actions, once they are formulated on \(\tilde{\Sigma}\). Section 5 shows how the simplest \(D = 10,11\) extended superspaces are relevant to construct a manifestly invariant WZ term, both for the Green–Schwarz superstring [13,33] (which we will complete with an additional contribution), and for the supermembrane. We shall recover there the results of [16] and compute the topological charges which, in our approach, correspond to the new group variables. The question of the linearity of the group action is seen in Section 5.1 to be associated with a coboundary election. Sections 6 and 8 show how the case of the IIA \(Dp\)-branes and M5-brane may also be treated within the same framework, i.e. how branes containing vector and tensor fields on \(W\) may be defined.

\(^1\) For a detailed account of quasi-invariance, Noether currents, cohomology and extensions, see Ref. [26,32].

\(^2\) This is not always possible. When the group \(G\) is simple, the extension appears only at the loop algebra (of charge densities) level, as for the \(\text{su}(2)\) Kac–Moody algebra for a WZW model, and disappears for the algebra of charges, as required by Whitehead’s lemma.

\(^3\) Although it may be argued that these invariant terms should no longer be called WZ terms, we shall retain this name for them.
directly on suitably extended superspaces. We shall argue, in fact, that the picture is
general and that suitable target superspaces exist on which to define all the fields
appearing in the p-brane actions, including the various vector (see also Ref. [22]),
tensor, etc., world-volume fields. This is tantamount to establishing a general fields/extended
superspace democracy in which the world-volume fields and the extended
superspace variables are on the same footing, as was already the case for the minimal
branescan. Indeed this correspondence between coordinates and fields has occasionally
been discussed in the past in other contexts (see Refs. [34–37]). Section 7 contains a
brief discussion of the origin of the contributions to the Noether charges in the D-branes
case [38] in our approach. Finally, an appendix complements the general theory of
non-central extensions of superspace in Section 3 and gives the proof of some needed
\( \Gamma \)-matrix identities.

2. Central extensions and their superspaces

2.1. Standard superspace as a central extension

Let \( \theta \) be an arbitrary Grassmann spinor in a \( D \)-dimensional space-time. Its components \( \theta^\alpha \) (2\(^{[D/2]}\) where \( [D/2] \) denotes the integer part of \( D/2 \), or \( 2^{(D/2)-1} \) in the Weyl case) determine an abelian group of supertranslations, generically denoted \( \text{sTr}_D \), with group composition law

\[
\theta^\alpha \theta^\beta = \theta^\gamma + \theta^\alpha.
\]

When the Lorentz part is considered explicitly, there is an action \( \rho \) of \( \text{Spin}(1,D-1) \) on \( \text{sTr}_D \) and the relevant group becomes \( \text{sTr}_D \ast \text{Spin}(1,D-1) \), where \( \ast \) indicates semidirect product. Then (1) is replaced by

\[
\theta^\alpha = \theta^\alpha + \rho(A) \theta, \quad A' = AA',
\]

where \( A \in \text{Spin}(1,D-1) \) and \( \rho(A) \) is the appropriate spin representation. The spinor \( \theta \) is often restricted to be of some specific type, usually minimal (e.g., Majorana (M),
Weyl (W) or Majorana–Weyl (MW), when possible); it may carry an additional index
\( i=1,\ldots,N \) if there is more than one supersymmetry. Associated with (1) is the abelian
Lie superalgebra \( (D_a,D_b) = 0 \), which can also be described in terms of the left-invariant (LI) one-forms \( \Pi^a = d\theta^a \) and the trivial Maurer–Cartan (MC) equation

\[
d\Pi^a = 0.
\]

Extending \( \text{sTr}_D \) by the Minkowski translations \( x^\mu, \mu = 0,\ldots,D-1 \) leads to standard
(rigid) superspace [25,26]. Let us adopt the free differential algebra (FDA)\(^5\) point of

\(^5\)Since we shall be considering left-invariant (LI) generators and forms, we shall use here \( D \)'s (rather than
\( Q \)'s) to denote the generators of the right translations (the \( Q \)'s being realized as the right-invariant (RI)
generators of the left translations). This distinction is of course irrelevant for an abelian group such as (1) but it
is not so when non-abelian parts are added (nevertheless, the corresponding structure constants differ only in a
sign). Furthermore, LI and RI generators commute, \( (Q,D) = 0 \). We may look at the \( D \)'s as covariant
derivatives and at the \( Q \)'s as the generators of the (left) supersymmetry transformations; see Section 4.

\(^6\)The term refers to an algebra generated by differential forms which is closed under the action of \( d \) [39].
For early physical applications of FDA in supersymmetry see [40,41] and references therein.
view to discuss the extension problem, since forms are especially convenient in the
construction of actions for extended objects.

Let $\theta^a$ be Majorana, and consider the two-form $\pi^a = \pi^\alpha \wedge \pi^\beta$ on sTr$_D$. It
defines a non-trivial CE two-cocycle on the superalgebra of sTr$_D$, i.e. it is left-invariant
(LI), closed and not given by the differential of a LI one-form. Since by construction the
two-cocycle transforms as a Lorentz vector, it is consistent to extend the FDA (3) by a
one-form $\pi^\mu$ such that

$$d\pi^\mu = \frac{1}{2} (C\Gamma^\mu)_{a\beta} \pi^a \pi^\beta$$

(we omit the wedge product henceforth). The above extension immediately implies
$[D_a, D_b] = (C\Gamma^\alpha)_{a\beta} \chi^\alpha$, with $\chi^\alpha$ central. One still has to relate the newly introduced
one-form to the coordinate $x^\mu$. We define

$$\pi^\mu = dx^\mu + \frac{1}{2} (C\Gamma^\mu)_{a\beta} \theta^a d\theta^\beta$$

and choose the transformation law for $x^\mu$ so that $\pi^\mu$ is LI

$$x'^\mu = x^\mu + x^\mu - \frac{1}{2} (C\Gamma^\mu)_{a\beta} \theta^a d\theta^\beta.$$  

This gives rigid superspace $\Sigma$, parametrized by $(\theta^a, x^\mu)$ and with group law given by
(1) and (6).

The above simple example exhibits already the key features of the extension
algorithm. Given a particular FDA to be extended, one identifies in general a non-trivial
two-cocycle of a desired Lorentz covariant nature and introduces a new LI one-form, the
differential of which is given by the cocycle. The new form (here, (5)) together with the
MC equations (here, Eqs. (3) and (4)) automatically define by duality an extended Lie
algebra. The new LI one-form is given by the sum of the differential of the new group
parameter and the potential one-form of the CE two-cocycle on sTr$_D$, which is not LI.
Finally, the transformation properties of the new coordinate are fixed so as to guarantee
the left invariance of the new one-form, while those of the original manifold are
unmodified. The additional one-form can be made LI only if it is defined on the extended
superspace manifold $\Sigma$. The new (central) generator, associated with translations along the new coordinates, modifies the r.h.s. of the original commutators of the
algebra. Since adding (4) to (3) involves a central extension, we could have introduced
a dimensionful constant as a factor in the r.h.s. of (4). By not doing so, the dimensions
of $\pi^\mu$ are fixed to be $[\pi^\alpha] = [\theta^a]$. We shall, as usual, take $[\theta^a] = L^1[1]$ so that
$[\pi^\mu] = L$.

If we add the Lorentz group, the result must reflect the action $\sigma$ of Spin(1, D − 1) on
the extension cocycle (see, e.g., Ref. [26], Section 5.3), but we shall not consider explicilty the effect of the simple part of the algebra which, apart from extracting the
various tensor-valued second cohomology groups from that of the trivial ($\sigma = 0$) action
$H^2_s(\text{Tr}_D)$ (see below), plays no essential rôle in our discussion once only Lorentz
covariant objects are used. Thus, central means, where appropriate, central up to
Lorentz transformations.

--

The value of this constant determines the specific element in cohomology space that characterizes the central extension.
The extension procedure described above can be applied more than once – there are two basic patterns one may follow in this case. One can start in each step with the same original manifold sTr, and keep adding two-cocycles and central generators or, in each step, one can consider the result of the previous extension as the starting manifold. In the first case (Section 2.2) all new generators remain central and appear only at the r.h.s. of the original (D,D) anticommutator. In the second case, a richer structure emerges since the generators introduced at each step can, in principle, modify all previous commutators. We shall give the details of this second construction in Section 3.

2.2. Maximal central extensions of superspace

Let θα be Majorana. We may obtain additional Lorentz tensors, leading to new central charges, by considering

\[ d\Pi^{\mu_1\cdots\mu_\rho} = \frac{1}{p!}(C\Gamma^{\mu_1\cdots\mu_\rho})_{\alpha\beta}\Pi^{\alpha\beta}, \]

\[ \left( \Gamma^{\mu_1\cdots\mu_\rho} = \Gamma^{[\mu_1,\mu_2}\cdots,\Gamma^{\nu]}_{\mu_\rho} \right) = \frac{1}{p!}\epsilon_{\mu_1\cdots\mu_\rho}\Gamma^{\nu_1}\cdots\Gamma^{\nu_p}, \]

(7)

where \( C\Gamma^{\rho}C^{-1} = -\Gamma^{\rho}' \). The antisymmetry in the Lorentz indices is needed to rule out trivial dependences coming from the fact that \( \{\Gamma^{\mu},\Gamma^{\nu}\} = 2\eta^{\mu\nu} \). The left invariance of the new forms in (7) requires new group parameters \( \varphi^{\mu_1\cdots\mu_\rho} \) so that (cf. (5))

\[ \Pi^{\mu_1\cdots\mu_\rho} = d\varphi^{\mu_1\cdots\mu_\rho} + \frac{1}{p!}(C\Gamma^{\mu_1\cdots\mu_\rho})_{\alpha\beta}\theta^\alpha\theta^\beta. \]

(8)

The superalgebra generator (L vector field) 2, corresponding to \( \Pi^{\mu_1\cdots\mu_\rho} \), is realized by \( Z_{\mu_1\cdots\mu_\rho} = \partial_\theta\varphi^{\mu_1\cdots\mu_\rho} \) on the extended group manifold.

At this stage there are no restrictions coming from the Jacobi identity, equivalent to \( d(d\Pi^{\mu_1\cdots\mu_\rho}) = 0 \), which follows trivially from \( d\Pi^{\alpha} = 0 \). This is an alternative way of stating that the \( p \)-tensor-valued mapping on \( s\text{Tr}_D \otimes s\text{Tr}_D \),

\[ \xi^{\mu_1\cdots\mu_\rho}(\theta',\theta) = \theta^\alpha(C\Gamma^{\mu_1\cdots\mu_\rho})_{\alpha\beta}\theta^\beta, \]

(9)

satisfies trivially the two-cocycle condition

\[ \xi(\theta,\theta') + \xi(\theta + \theta',\theta'') = \xi(\theta,\theta' + \theta'') + \xi(\theta',\theta''). \]

(10)

The symmetry of \( (C\Gamma^{\mu_1\cdots\mu_\rho})_{\alpha\beta} \) is needed to prevent the two-cocycle (9) from being trivial (i.e. a two-coboundary), since \( \eta(\theta) = \theta^\alpha(C\Gamma^{\mu_1\cdots\mu_\rho})_{\alpha\beta}\theta^\beta \) on \( s\text{Tr}_D \), which might generate \( \xi \) through \( \xi(\theta',\theta) = \eta(\theta') - \eta(\theta') - \eta(\theta) \), is identically zero. Thus, (9) defines a non-trivial extension. For a given space-time dimension D, the symmetry condition restricts the rank of the tensors that are allowed in (7). Hence, the problem of finding all central extensions of the algebra \( (D_D, D_D) = 0 \) (or of the Lie FDA (3)) is reduced to finding a basis of the symmetric space \( \Pi^{\alpha} \otimes \Pi^{\beta} \) in terms of tensors \( (C\Gamma^{\mu_1\cdots\mu_\rho})_{\alpha\beta} \) symmetric in \( \alpha,\beta \); they define the Lie algebra CE two-cocycles \( \Pi^{\alpha}(C\Gamma^{\mu_1\cdots\mu_\rho})_{\alpha\beta}\Pi^{\beta} \).

\[^{2}\text{We adopt } C = C_8 \text{ for simplicity. By not considering } C, \Gamma^\mu C_8^{-1} = C_8^\mu \text{ we rule out, e.g., the pseudoMajorana spinors that exist for } D = 8,9 \pmod{8} \text{ (see Ref. [42]).}\]
When $D$ is even, the space of matrices with indices $(\alpha \beta)$ is $2^D$-dimensional. Since $2^D = \sum_{p=0}^{D} \binom{D}{p}$, a basis for this space is provided by the $(2^D - 1)$ matrices given by the Lorentz tensors $\Gamma^{\mu_1 \cdots \mu_p}$ of rank $1 \leq p \leq D$ plus the unit matrix. For $D$ odd, the spinors have dimension $2^{(D-1)/2}$ and, since $2^{D-1} = \sum_{p=0}^{(D-1)/2} \binom{D-1}{p}$, a basis is provided by the $(2^{D-1} - 1)$ matrices given by the tensors $\Gamma^{\mu_1 \cdots \mu_p}$ of rank $1 \leq p \leq (D-1)/2$ plus the unit matrix. The difference is a consequence of the fact that, for any $D$,

$$\Gamma^{\mu_1 \cdots \mu_p} D^{D+1} \alpha \epsilon^{\mu_1 \cdots \mu_p} \epsilon_{\mu_{p+1} \cdots \mu_p},$$

where $\Gamma^{D+1}$ is the chirality matrix. For $D$ odd, $\Gamma^{D+1} \alpha 1$, and only the tensors of rank $0 \leq p \leq (D-1)/2$ are linearly independent.

For $D$ even, $C \Gamma^{\mu_1 \cdots \mu_p}$ satisfies (see, e.g., Ref. [43])

$$\varepsilon = (-1)^{(p-1)(p-2)/2} (C \Gamma^{\mu_1 \cdots \mu_p})^T, \quad \mu = 0, 1, \ldots, D - 1$$

Thus, $\epsilon = 1 (-1)$ for $D = 2, 4, 6, 8 \mod 8$ so that $(C \Gamma^{\mu_1 \cdots \mu_p})_{\alpha \beta}$ is symmetric for $p = 1, 2 \mod 4$ if $D = 2, 4 \mod 8$ and for $p = 3, 4$ if $D = 6, 8 \mod 8$. For $D$ odd, it turns out that the same condition, $\epsilon = (-1)^{(p-1)(p-2)/2} = 1$, holds for $D = 3 \mod 4$ with $\epsilon = -\sqrt{2} \cos \frac{\pi}{4}(D+1)$.

The number of cohomology spaces $H_s^{2}(sTr_{D} \circ Spin(1, D - 1))$ for various $sTr_{D}$ groups is given in the table. As a two-form, the various CE two-cocycles are given by $d\theta (C \Gamma^{\mu_1 \cdots \mu_p}) d\theta$. The corresponding new generators $Z_{\mu_1 \cdots \mu_p}$ are all central, as is $X_\mu$ itself. They are on the same footing and may be thought of as generalised momenta. Each of the resulting extensions defines an extended superspace group; we will denote them generically by $\Sigma$.

The table also includes the cases in which the spinor is Majorana–Weyl or complex (Dirac and Weyl). If the spinor is complex the independent tensors $\Gamma^{0} \Gamma^{\mu_1 \cdots \mu_p}$ may appear. The effect of considering Weyl spinors is taken into account by introducing a chiral projector ($\mathcal{P}_\alpha$, say).

The different extended supersymmetry algebras can be easily found from the results in the table. We shall only give below two examples which contain formulae that will be explicitly used later on. To avoid cumbersome factorials, we use a normalization of the generators which is tantamount to defining the duality relations by $\Pi^{\mu_1 \cdots \mu_p} (Z_{\nu_1 \cdots \nu_p}) = \frac{1}{m} \epsilon^{\mu_1 \cdots \mu_p} \epsilon_{\nu_1 \cdots \nu_p}$ so that $\Pi^{\mu_1 \cdots \nu_p} (C \Gamma^{\nu_1 \cdots \nu_p} Z_{\nu_1 \cdots \nu_p}) = C \Gamma^{\mu_1 \cdots \nu_p}$.

### 2.3. Applications

#### 2.3.1. N = 1 theory extended superspace

For $D$ even, the basic spinors in (1) may be reduced to $2^{D/2-1}$-dimensional Weyl spinors, and the discussion of the possible $H_s^{2}(sTr_{D} \circ Spin(1, D - 1))$ spaces must take this into account. Let $D = 2 \mod 8$ and let $\theta^\alpha$ be MW. The symmetry of
\( (C \Gamma^{\mu_1 \cdots \mu_s} \mathcal{P}_a)_{\alpha \beta} \) is now achieved if both \( C \Gamma^{\mu_1 \cdots \mu_s} \) and \( C \Gamma^{\mu_1 \cdots \mu_s} \Gamma^{E+1} \) (or, on account of (11), \( C \Gamma^{\mu_1 \cdots \mu_s} \cdots \)) are symmetric. Hence, there are central charges for \( D = 2, p = 1 \) and \( D = 10, p = 1,5,9 \) (i.e. \( p = 1 \mod 4 \)). As a result, the \( D = 10, N = 1 \) extended superspace algebra has the form
\[
\{ D_{\alpha}, D_{\beta} \} = (C \Gamma^{\mu_1} \mathcal{P}_a)_{\alpha \beta} X_{\mu} + (C \Gamma^{\mu_1 \cdots \mu_s} \mathcal{P}_a)_{\alpha \beta} Z_{\mu_1 \cdots \mu_s},
\]
\[
+ (C \Gamma^{\mu_1 \cdots \mu_s} \mathcal{P}_a)_{\alpha \beta} Z_{\mu_1 \cdots \mu_s},
\]
Due to \( \mathcal{P}_a \) and to (11), the first and last term in the r.h.s may be grouped into a single one, \( (C \Gamma^{\mu_1} \mathcal{P}_a)(X_{\mu} + Z_{\mu}) \); classically, \( Z_{\mu} \) may be absorbed by redefining \( X_{\mu} \) and the previous analysis shows that the vector-valued cohomology space is one-dimensional. The second term may be rewritten as \( (C \Gamma^{\mu_1} \mathcal{P}_a)_{\alpha \beta} Z_{\mu_1 \cdots \mu_s} \) where \( Z_{\mu_1 \cdots \mu_s} \) is a self-dual 5-tensor \( \mathcal{D}_{\mu_1} \), \( Z_{\mu_1 \cdots \mu_s} = \frac{1}{2}(Z_{\mu_1 \cdots \mu_s} + \epsilon_{\mu_1 \cdots \mu_s} \mathcal{P}_{\mu_1 \cdots \mu_s} \mathcal{P}_{\mu_1 \cdots \mu_{10}}) \), with half the number of components of \( Z_{\mu_1 \cdots \mu_s} \). As a result, the degrees of freedom in Eq. (13) match: \( \frac{16}{2} + 16 = 136 + \frac{1}{2} \left( \frac{10}{5} \right) = 32 \) (see Table 1). But in general \( Z_{\mu} \) cannot be reabsorbed, since the Green–Schwarz action for the heterotic superstring produces such a contribution to the algebra [12], of an origin different from that of \( X_{\mu} \). Mathematically, this corresponds to the fact that the group parameters are different for \( X_{\mu} \) (translations \( x^{\mu} \)) and \( Z_{\mu} (\phi^\mu) \); they are locally equivalent, much in the same way \( \mathbb{R} \sim S^1 \) locally, but they are different globally. We may, however, achieve the symmetry under the exchange of \( X_{\mu} \) and \( Z_{\mu} \) (say) when the 9-direction is a circle of radius \( R \). Then the spectra of \( X_{\mu} \) and \( Z_{\mu} \) are isomorphic under the T-duality exchange \( R \rightarrow 1/R \) (see Refs. [44, 45]).

The FDA form of the \( D = 10, N = 1 \) superalgebra (13) is given by the MC relations
\[
d \Pi^\alpha = 0, \quad d \Pi^\mu = \frac{1}{4} (C \Gamma^\mu)_{\alpha \beta} \Pi^\alpha H^\beta, \]
\[
d \Pi^{\mu_1 \cdots \mu_s} = \frac{1}{2} (C \Gamma^{\mu_1 \cdots \mu_s})_{\alpha \beta} \Pi^{\alpha H^\beta}, \]
where \( \Pi^\alpha, \Pi^\mu \) and \( \Pi^{\mu_1 \cdots \mu_s} \) are defined as \( (\alpha = 1, \ldots, 32) \)
\[
\Pi^\alpha = \mathcal{P}_a d \theta^\alpha, \quad \Pi^\mu = dx^{\mu} + \frac{1}{2} (C \Gamma^\mu)_{\alpha \beta} d \theta^\alpha d \theta^\beta, \]
\[
\Pi^{\mu_1 \cdots \mu_s} = d \phi^{\mu_1 \cdots \mu_s} + \frac{1}{2} (C \Gamma^{\mu_1 \cdots \mu_s})_{\alpha \beta} d \theta^\alpha H^\beta. \]
If \( Z_{\mu} \) is included separately, this introduces a further extension which requires adding a new LI form associated with it. \( \Pi^{(\phi)}_{\mu}, d \Pi^{(\phi)}_{\mu} = \frac{1}{2} (C \Gamma^\mu)_{\alpha \beta} d \theta^\alpha d \theta^\beta \) (we have written the index down for consistency with later notation, as in Section 5.1). At the group level this means that the MW translations generate two types of transformations i.e. one has to distinguish between the translations \( x^{\mu} \) and the \( \phi^\mu \), some of which may be compact, in which case the corresponding group law expression should be understood locally.

2.3.2. IIA theory centrally extended superspace

Let us consider now the \( H_3^D (x T_{10} \ast \text{Spin}(1,9), \text{IIA}) \) spaces. The IIA superalgebra is the \( D = 10 \) algebra associated with two 16-dimensional spinors of opposite chiralities which may be combined into a Majorana spinor. Then (see Table 1), the \( \text{IIA theory maximally extended algebra} \) [28] is found to be
\[
\{ D_{\alpha}, D_{\beta} \} = (C \Gamma^\mu)_{\alpha \beta} X_{\mu} + (C \Gamma^{\mu_1 \mu_2})_{\alpha \beta} Z_{\mu_1 \mu_2} + (C \Gamma^{\mu_1 \cdots \mu_5})_{\alpha \beta} Z_{\mu_1 \cdots \mu_5},
\]
\[
+ (C \Gamma^{11})_{\alpha \beta} Z_{11} + (C \Gamma^{11})_{\alpha \beta} Z_{11} + (C \Gamma^{11})_{\alpha \beta} Z_{11} Z_{11},
\]
\[
\]
Table 1

Some Lie algebra second cohomology groups for $sTr$, minimal spinors are in boldface. $\alpha$ is the complex dimension of a Dirac-spinor, equal to the real dimension of Majorana spinors for $D = 2,3,4$ \text{mod} 8. The fourth column gives the dimension of the spinor indicated. The fifth and sixth column give the ranks for which $(C\Gamma^{\mu_1 \cdots \mu_p})_\alpha$ or $(C\Gamma^{\mu_1 \cdots \mu_p})_{\alpha\beta}$ are symmetric (as deduced from (12)) and the dimension of these Lorentz tensors: $C$ itself is symmetric in $D = 6,7,8$ \text{mod} 8. The seventh and eighth columns do the same for the additional tensors $(\Gamma^\nu\Gamma^{\mu_1 \cdots \mu_p})$ appearing in the complex spinor case. These hermitian (adding $i$ when needed) tensors are limited by duality (Eq. (11)) in the odd ($D = 7$) case and to odd rank by the presence of $\mathcal{P}^\perp$ in the Weyl case. The $\frac{1}{2}$ indicates halving due to self-duality. The number of real cohomology groups $H_2^\alpha(sTr \times Spin(1, D - 1))$ is given by the first number in the last column. These spaces are the relevant (i.e. tensorial) ones, once the Lorentz symmetry is considered since in this case $sTr \times Spin(1, D - 1)$ is given (rather than $sTr$) is the group to be extended. The action $\sigma$ of $Spin(1, D - 1)$ on the extension cocycles is automatically taken into account by using only Lorentz covariant objects for them. The bracketed number in the last column ignores the Lorentz part and, as a result, $\dim H_2^\alpha(sTr) = \left(\frac{n'}{2}\right) + n'$ since the elements of $sTr$ are odd (for an ordinary $n'$-dimensional abelian group $\dim H_2^\alpha = \left(\frac{n'}{2}\right)$. The number $\left(\frac{n'}{2}\right)$ is given nevertheless since it serves as a check on the degrees of freedom; it is equal to the sum of the total real dimensions in the sixth and eighth columns.

</table>
since the tensor spaces \( \{ \Gamma^\mu_1 \ldots \mu_s \} \) and \( \{ \Gamma^{\mu_1 \ldots \mu_D} \} \) are isomorphic by Eq. (11). Notice that \( X_\mu \) and \( Z_\mu \) belong to different cohomology classes (their corresponding two-cocycles are not cohomologous due to the presence of \( \Gamma^{11} \) in the \( Z \) term). The associated IIA Lie FDA, involving the LI one-forms dual to the generators in (16), is given by
\[
d\Pi^\alpha = 0, \\
d\Pi^\mu = \frac{1}{2} (C \Gamma^\mu)_{\alpha\beta} \Pi^\alpha \Pi^\beta, \\
d\Pi^C_{\alpha\beta} = \frac{1}{2} (C \Gamma^{\alpha\beta})_{\alpha\beta} \Pi^\alpha \Pi^\beta, \\
d\Pi^{\mu_1 \ldots \mu_s} = \frac{1}{2} (C \Gamma^{\mu_1 \ldots \mu_s})_{\alpha\beta} \Pi^\alpha \Pi^\beta, \\
d\Pi^{\mu_1 \ldots \mu_s} = \frac{1}{2} (C \Gamma^{\mu_1 \ldots \mu_s\Gamma^{11}})_{\alpha\beta} \Pi^\alpha \Pi^\beta, \\
d\Pi = \frac{1}{2} (C \Gamma^{11})_{\alpha\beta} \Pi^\alpha \Pi^\beta. \tag{17}
\]

The new group parameters define the IIA theory centrally extended superspace, parametrized by the coordinates \((u, x, w, w, w, w, w)\).

3. Non-central extensions and their superspaces

We start now from standard rigid superspace, Eqs. (3), (4) for real, odd translations. To keep the discussion as general as possible, we rescale \( \Pi^\alpha, \Pi_{\mu_1 \ldots \mu_s} \) by an arbitrary dimensionless constant \( a \), so that (4), (7) become
\[
d\Pi^\alpha = a (C \Gamma^\alpha)_{\alpha\beta} \Pi^\alpha \Pi^\beta, \\
d\Pi_{\mu_1 \ldots \mu_s} = a_0 (C \Gamma_{\mu_1 \ldots \mu_s})_{\alpha\beta} \Pi^\alpha \Pi^\beta. \tag{18}
\]

Let us fix \( p \) and consider the resulting extended superspace, parametrized by \((\theta^a, x^\mu, \varphi^a, \varphi^{\mu_1 \ldots \mu_s}, \varphi^\mu_1 \ldots \mu_s, \varphi^\mu_1 \ldots \mu_s, \varphi)\). The IIB case with \( \Pi^a \equiv \theta^a \) is treated similarly by noticing that the presence of \( \epsilon_{ij} \) allows for \( C \Gamma_{\mu_1 \mu_2 \mu_3} \theta^{\mu_1 \mu_2 \mu_3} \), which is skew-symmetric.

\[\text{8} \quad \text{Primed indices are understood to be symmetrised (with unit weight).}\]
straint, on both $D$ and $p$, is a new feature – the non-triviality of (9) only restricted $p$. We introduce now a new one-form $\Pi_{\mu_1\ldots\mu_{p-1}a_1^{i_1}}$ with

$$d\Pi_{\mu_1\ldots\mu_{p-1}a_1^{i_1}} = a_1 \left( (C\Gamma_{\mu_1\ldots\mu_{p-1}})_{\beta\alpha_2} \Pi^{\beta} + \frac{a_3}{a_0} (C\Gamma^\nu)_{\alpha_1\alpha_2} \Pi_{\nu\mu_1\ldots\mu_{p-1}a_1^{i_1}} \right)$$

(21)

(for $p=1$ the coefficient of the second term can be arbitrary, see Section 5.1). The above MC equation implies that both $[D, X]$ and $[D, Z_{\mu_1\ldots\mu_{p-1}a_1^{i_1}}]$ are modified by a term proportional to $Z_{\mu_1\ldots\mu_{p-1}a_1^{i_1}}$, the latter being the only central generator at this stage ($Z_{\mu_1\ldots\mu_{p-1}a_1^{i_1}}$) is central because, by construction, $\Pi_{\mu_1\ldots\mu_{p-1}a_1^{i_1}}$ cannot appear at the r.h.s. of a MC equation expressing the differential of a LI form). This is a general feature of the extension scheme in this section: at any stage in the chain of extensions, the only central generator present is the last one introduced. Thus, each extension is central, but the resulting algebra/group is not a central extension of superspace: all generators but the last one have non-zero commutators as a consequence of the subsequent extensions.

A second feature here is that successive extensions substitute one spinorial index for a vectorial one, preserving the total number of indices. The chain ends with the introduction of a generator with $p$ spinorial indices.

Repeating the above procedure, one finds that the next three extensions are in some sense exceptional (see (22) below), while the one introducing five spinorial indices and all others after it follow a pattern which can be used to derive a recursion formula. Skipping the somewhat involved algebra (see Appendix A), we first list the results for the next three extensions:

$$d\Pi_{\mu_1\ldots\mu_{p-2}a_1^{i_1}a_2^{i_2}} = a_2 \left( (C\Gamma_{\nu\mu_1\ldots\mu_{p-2}})_{\alpha_1\alpha_2} \Pi^{\nu} + \frac{a_3}{a_0} (C\Gamma^\nu)_{\alpha_1\alpha_2} \Pi_{\nu\mu_1\ldots\mu_{p-2}a_1^{i_1}a_2^{i_2}} \right)$$

$$- \frac{a_2}{a_1} (C\Gamma^\nu)_{\alpha_1\alpha_2} \Pi_{\nu\mu_1\ldots\mu_{p-2}a_1^{i_1}a_2^{i_2}} \Pi^\beta$$

$$- 8 \frac{a_2}{a_1} (C\Gamma^\nu)_{\alpha_1\alpha_2} \Pi_{\nu\mu_1\ldots\mu_{p-2}a_1^{i_1}a_2^{i_2}} \Pi^\beta$$

$$d\Pi_{\mu_1\ldots\mu_{p-3}a_1^{i_1}a_2^{i_2}a_3^{i_3}} = a_3 \left( (C\Gamma^\nu)_{\alpha_1\alpha_2} \Pi_{\nu\mu_1\ldots\mu_{p-3}a_1^{i_1}a_2^{i_2}a_3^{i_3}} \Pi^\alpha \right)$$

$$+ \frac{5a_2}{4a_1} (C\Gamma^\nu)_{\alpha_1\alpha_2} \Pi_{\nu\mu_1\ldots\mu_{p-3}a_1^{i_1}a_2^{i_2}a_3^{i_3}} \Pi^\beta$$

$$+ \frac{a_2}{4a_1} (C\Gamma^\nu)_{\alpha_1\alpha_2} \Pi_{\nu\mu_1\ldots\mu_{p-3}a_1^{i_1}a_2^{i_2}a_3^{i_3}} \Pi^\beta$$

---

For $p=1$, the one-form in the l.h.s. of (21) becomes $H_p$ – notice that this is unrelated to $H^n$ (so that, e.g., $dH_p$ is non-zero). In general, we will not raise or lower the Lorentz indices of forms, their position being used to distinguish between different types of them as in [19].
\[ d\Pi_{\mu_1\ldots\mu_{p-1}\alpha_1\ldots\alpha_k} = a_k \left( (\mathcal{G}^\rho)_{\alpha_1\alpha_2} \Pi_{\rho\mu_1\ldots\mu_{p-1}\alpha_1\alpha_2} \right)^\rho \]
\[ - \frac{48a_k a_{\alpha_2}}{5a_1 a_3} (\mathcal{G}^\rho)_{\alpha_1\beta} \Pi_{\rho\mu_1\ldots\mu_{p-1}\alpha_1\alpha_2} \Pi^{\alpha_2} \]
\[ - \frac{12a_k a_{\alpha_2}}{5a_1 a_3} (\mathcal{G}^\rho)_{\alpha_1\alpha_2} \Pi_{\rho\mu_1\ldots\mu_{p-1}\beta\alpha_1\alpha_2} \Pi^{\beta} \] (22)

(the \(a_k\)'s in the r.h.s. normalise the \(\Pi\)'s with \(k\) spinorial indices. For the remaining extensions, which introduce one-forms with five or more spinorial indices, one establishes the following recursion formula:

\[ d\Pi_{\mu_1\ldots\mu_{p-1}(k+2)\alpha_1\ldots\alpha_{k+2}} = a_{k+2} \left( (\mathcal{G}^\rho)_{\alpha_1\alpha_2} \Pi_{\rho\mu_1\ldots\mu_{p-1}(k+2)\alpha_1\alpha_2} \right)^\rho \]
\[ + \lambda_{k+2}^{(k+2)} (\mathcal{G}^\rho)_{\alpha_1\beta} \Pi_{\rho\mu_1\ldots\mu_{p-1}(k+2)\alpha_1\alpha_2} \Pi^{\alpha_2} \]
\[ + \lambda_{k+2}^{(k+2)} (\mathcal{G}^\rho)_{\alpha_1\alpha_2} \Pi_{\rho\mu_1\ldots\mu_{p-1}(k+2)\beta\alpha_1\alpha_2} \Pi^{\beta} \] (23)

where

\[ \lambda_{k+2}^{(k+2)} = - \frac{a_k}{a_{k+1}} \left( \frac{2}{\lambda_k (k+1)} + \frac{k}{\lambda_k (k+1)} \right), \quad \lambda_{k+2}^{(k+2)} = - \frac{a_k}{a_{k+1}} \frac{k+1}{\lambda_k (k+1)} \] (24)

Notice that the above recursion starts at \(k = 3\), which implies \(p \geq 5\). On the other hand, the maximum value of \(p\) (of interest to us) for which (20) holds true is \(p = 5\), i.e. (23) is relevant here only for \(k = 3, p = 5\). It is easily checked that

\[ \left[ \Pi_{\mu_1\ldots\mu_{p-1}\alpha_1\ldots\alpha_k} \right] = L^{1+\frac{k}{2}} \]

We give related explicit results, for \(p = 1, 2\), in Section 5.

4. Structure of the new superspaces and Noether currents

4.1. Fibre bundle structure

All extended superspaces have a natural bundle structure, in which the basis is the group to be extended and the fibre is the group by which we extend. For instance, superspace \(\Sigma\) itself and the various extensions \(\Sigma\) in Section 2.2 may be considered as the total spaces of principal bundles over the sTr\(_D\)'s of the specific theory. The two-forms which define the extensions are curvatures of invariant connections valued on the central algebras by which sTr is extended. The \(D\)'s are then the horizontal lifts of the vector fields \(\partial/\partial x^\alpha\) on the specific base manifold sTr\(_D\); this justifies the ‘covariant derivative’ name which may be given to the \(D\)'s in the algebra of the \(\Sigma\)'s. Similar considerations apply at any step in the chain of extensions in Section 3. From this point of view, after the last step, one has a bundle structure with the last coordinate in the fibre and all the rest in the base. As we show below, there is also another relevant bundle structure with \(\Sigma\) in the base and all new coordinates in the fibre.

Let us now discuss the general case treated in Section 3. \(\Sigma\) is parametrised by the coordinates \((\theta^\alpha, x^p, \varphi_{\mu_1\ldots\mu_{p-1}\alpha_1\ldots\alpha_p})\). We will denote them collectively
by the row vector \( \phi = (z^a, \varphi) \) where \( z \) parametrizes the base (superspace \( \Sigma \)) and \( \varphi \) the fibre (the space of all new coordinates). Referring to this block form, we will say that the superspace part is ‘two-dimensional’ while the fibre part has ‘dimension’ \( p + 1 \). The LI one-forms that reduce to the differentials of these coordinates at the identity will be denoted by \( \Pi = (H^\alpha, \Theta_\alpha) \) and the dual LI vector fields by the column vector \( Z = (D_\mu, Y^\nu) \) (\( \tau \) denotes matrix transposition). The corresponding RI objects will carry an additional hat.

Under a right group transformation, \( g \to gg' \), \( Z \) transforms like \( Z \to T''Z \), \( T' \) being a matrix of (primed) functions on the group, called the adjoint representation. We have

\[
T'' = T'T, \quad Z \cdot T|_e = \rho_{ad}(Z),
\]

\( \rho_{ad}(Z) \) being the adjoint representation of \( Z \), given by the structure constants. Inspection of the MC equations then reveals that \( T \) is a lower triangular matrix with units along the diagonal. We put accordingly

\[
\left(\begin{array}{c} D \\ Y \end{array}\right) \to \left(\begin{array}{c} A'D + C'Y \\ B'Y \end{array}\right).
\]

The LI forms similarly transform according to \( \Pi \to \Pi(T')^{-1} \), i.e.

\[
( H, \ \Theta ) \to \left( HA^{-1}, \ -HA^{-1}CB^{-1} + \Theta B^{-1}\right).
\]

The Lie algebra valued one-form \( \omega = \Theta Y \) serves as a connection in the bundle. Indeed, one easily verifies that \( \omega \) is invariant under (27), (28) when \( T \) is restricted to the subgroup of the fibre \( (A = I, C = 0) \). The horizontal subspace is spanned by the kernel of \( \omega \), i.e. by the components of \( D \), the latter being the horizontal lifts of the standard superspace generators \( D_\mu^{(i)} = \partial x^\mu \), \( X_\nu^{(i)} = \partial x_\nu + \tfrac{1}{2}(C\bar{\Gamma}_\nu)_{\rho a} \partial \bar{\varphi}_a \).

In later applications, in Section 5, the explicit form of the matrix \( B^{-1} \) is needed – we present here a few remarks that facilitate its computation. Inspection of the r.h.s. of the MC equations for the new one-forms, in Section 3, shows that they always contain one new one-form, multiplied by a \( \Pi'^\alpha \) or \( \Pi'^\bullet \). For the dual Lie algebra this implies that the new generators commute among themselves and only have, in general, non-zero commutators with the superspace generators \( D_\mu, X_\nu \). In other words, the group by which we extend \( \Sigma \) is abelian (to begin with) and its generators acquire, as a result of the extension, non-zero commutators only with the superspace generators. The structure of the resulting Lie algebra is, in symbolic form,

\[
[ D, D ] \sim D + Y, \quad [ D, Y ] \sim Y, \quad [ Y, Y ] = 0.
\]
in the notation introduced earlier. For $T$, the expression
\[ T = e^{\phi^* \rho_{ad}(D_x)} = e^{\phi^* \rho_{ad}(D_\alpha) + \varphi_\gamma \rho_{ad}(Y^\gamma)} \]  
(31)
is well known. From the third of (30) though, we infer that the restriction of $\rho_{ad}^I(Y)$ to the fibre (i.e. to the sub-block corresponding to $B^\gamma$) is zero. Denoting this sub-block by $\rho_{ad}^{ij}(Y)$ we find for $B$
\[ B = e^{\phi^* \rho_{ad}^{ij}(D_\alpha) + x^\mu \rho_{ad}^{ij}(X^\mu)} \]  
(32)
where the matrices $\rho_{ad}^{ij}(D_\alpha)$ are given by the structure constants that appear in the explicit form of the second of (30). The interesting point here is that $B$ depends on $(\theta, x)$ only – the new variables enter in $T$ only through $A, C$.

4.2. Invariant actions for the minimal branescan

As already mentioned, part of the motivation for studying superspace extensions comes from their relevance in the construction of manifestly invariant $p$-brane actions. For the branes of the old branescan, WZ terms on $\Sigma$ have the form
\[ S_{WZ} = \int_W d^{p+1} \xi \, \mathcal{L}_{WZ} = \lambda \int_W \phi^* (b), \]  
(33)
where $b$ is defined\(^{10}\) as the potential of the closed $(p + 2)$-form $h$ on superspace
\[ h = (C \Gamma_{\mu_1 \ldots \mu_p})_{ab} \Pi^{a_1} \ldots \Pi^{a_p} \Pi^{a} \Pi^b, \quad db = h. \]  
(34)
$W$ in (33) is the $(p + 1)$-dimensional world-volume swept out by the $p$-brane, parametrized by $\{ \xi^I = (\tau, \sigma^1, \ldots, \sigma^p), i = 0, 1, \ldots, p \}$ and $\phi^*$ is the pullback of the embedding $\phi : W \to \Sigma$. The constant $\lambda$ is fixed by the requirement of $\kappa$-invariance of the total action [1] (we will ignore $\lambda$ henceforth). As is well known [1] (see also Ref. [2]), the closure of $h$ is equivalent to the condition (20) which we have seen to guarantee the existence of the non-central extensions of Section 3. Using the new LI one-forms available we may obtain a LI potential $\tilde{b}$ for $h$ on $\Sigma$. Its general form is
\[ \tilde{b} = \sum_{k=0}^p \Pi_{\mu_1 \ldots \mu_k \ldots} \Pi_{a_1 \ldots a_k} (b_{k} \Pi^{\mu_1} \ldots \Pi^{\mu_k} \Pi^{a_1} \ldots \Pi^{a_k}) \equiv \Theta_C \Lambda^C, \]  
(35)
where the last equation uses the notation of Section 3 and defines $\Lambda^C$. The $b_k$'s are numerical constants, determined by the second equation in (34). We check that $[\tilde{b}] = L^{p+1}$.

We compute now the explicit form for an invariant $\mathcal{L}_{WZ}$ in (33) (i.e. with $\tilde{b}$ instead of $b$). For a general one-form $\Pi$ we put $\phi^* (\Pi) = \Pi, d\xi^i$, so that
\[ \Pi^\alpha = \partial^\alpha \theta^\alpha, \quad \Pi^\mu = \partial^\nu x^\mu + a_i (C \Gamma_{\mu_1})_{a_\beta} \theta^a \theta^{b_i}. \]  
(36)
Eqs. (35) and (33) give for the Lagrangian
\[ \mathcal{L}_{WZ} = \Theta_C \Lambda^C, \]  
(37)
\(^{10}\)For an explicit form of the quasi-invariant $b$ on $\Sigma$ see Ref. [46].
where, expanding multi-indices and using the above notation,
\[ A_{\mu_1 \ldots \mu_{p-1} a_1 \ldots a_i} \equiv b_{i(} \epsilon^{(h \ldots j_1) \Pi_{j_1} \ldots \Pi_{j_{p-1}}^{a_1} \ldots \Pi_{j_{p-1} + 1}^{a_i})} . \quad (38) \]

4.3. Noether currents for the new symmetries

The invariance under translations of the action of the supersymmetric objects implies the existence of conserved currents. The integrals of the charge densities over a spacelike section of the world-volume give constants of the motion for the p-brane. When the action contains the standard WZ term, the Noether current includes a term coming from the quasi-invariance of the WZ term. This was used in [12] to find topological extensions of the supersymmetry algebra. When the action is replaced by the invariant \( \tilde{b} \), the Noether current receives now a contribution from the additional fields \( \phi^* (\varphi) \), which leads to the same result.

One can derive general expressions for the currents associated with the new generators. In the present case, where the relevant part of the Lagrangian is obtained by pulling back to \( W \) forms initially defined on \( \Sigma \), it is convenient to work on the extended superspace, where quantities have a direct geometrical interpretation, and to pull the result back to \( W \) at the end. To keep the discussion general, consider a manifold \( M \) which can serve as world-volume and a target space \( N \), of dimensions \( m, n \) respectively \((m < n)\) and an embedding \( \phi \) of \( M \) into \( N \), \( \phi : x \mapsto y(x) \) where \( \{x^i\} \ (\{y^j\}) \) are local coordinates on \( M \ (N) \). Consider furthermore an action \( S \) given by

\[ S = \int_M \phi^* (\alpha) , \quad (39) \]

where \( \alpha \) is a \( k \)-form on \( N \) and \( \phi^* \) is the pullback map associated with the embedding. We assume that the submanifolds \( x^0 = x^0_{\text{ini}}, x^0 = x^0_{\text{fin}} \) of \( M \) form its boundary \( \partial M \) – their embeddings in \( N \) are the initial and final configuration, respectively. The equations of motion are

\[ \delta_\gamma S = \int_M \phi^* (L_\gamma \alpha) = 0 , \quad (40) \]

where \( Y \) is an arbitrary vector field on \( N \) which vanishes on \( \phi(\partial M) \) – we denote their solutions generically by \( \phi_{\gamma} \). Proceeding along the lines of the standard derivation, with inner derivations taking up the role of the partials \( \partial / \partial \phi_{\gamma} \), one finds the equations of motion in the form

\[ \phi^* (i_Y d \alpha) = 0 , \quad (41) \]

where now \( Y \) is an arbitrary vector field, not necessarily vanishing on \( \partial M \). For a symmetry generated by \( Y_\alpha \), one obtains

\[ d(\phi^* (J_{\gamma t})) = 0 , \quad J_{\gamma t} \equiv i_{Y_\alpha} \alpha , \quad (42) \]

which is the current conservation equation. For a quasi-invariant Lagrangian, \( \phi^* (L_\gamma \alpha) = \phi^* (\alpha) \), the conserved current picks up a term in \( \Delta \), \( \phi^* (J_{\gamma t}) = \phi^* (i_{Y_\alpha} \alpha) \).

In the present case, \( (M, N, \alpha) \) correspond to \( (W, \Sigma, b) \). The variation of the total action from that of the new coordinates comes only from \( \mathcal{L}_{\text{WZ}} \), so that (41) gives

\[ 0 = \phi^* (i_Y d b) = \phi^* (i_Y h) , \quad (43) \]
where $Y$ is an arbitrary vector field along the fibre. Since $h$ is horizontal, the above equations of motion obtained from variations of the $\varphi_i$’s, are satisfied trivially, consistent with the appearance of the $\varphi_i$’s in the Lagrangian through exact differentials. For the Noether currents associated to translations along the new coordinates we have $Y_0 \to \tilde{Y}^A$ and (42) gives

$$d(\phi_i^A(J^A)) = 0, \quad J^A = i_Y \tilde{b}. \quad (44)$$

With $\tilde{b}$ as in (35) and $\tilde{Y}^A = (B^{-1})^A_c Y^C$ (see (29)), the second of (44) gives for $J^A$

$$J^A = (B^{-1})^A_d i_{Y^p} \Pi^e_C \Lambda^C = (B^{-1})^A_c A^C,$$

since $i_{Y^p} \Pi^e_C = \delta^D_C$. Notice that $J^A$ is, in this case, a form on $\Sigma$ rather than $\tilde{\Sigma}$. Effecting explicitly the pullback in the first of (44) we find

$$\partial_i j^{\lambda i} = 0, \quad j^{\lambda i}(\xi) \equiv (B^{-1})^A_c (\xi) A^C(\xi). \quad (46)$$

Finally, the conserved charges $Q^A$ are given by (expanding multi-indices)

$$Q^{\mu_1 \ldots \mu_p \ldots \lambda_1 \ldots \lambda_k} = \int_{W_p} d\sigma^1 \ldots d\sigma^p \sum_{m=0}^p (B^{-1})^{\mu_1 \ldots \mu_p \ldots \lambda_1 \ldots \lambda_k} \beta_m \beta_n \epsilon^{0 \ldots j_p} \times \Pi_{j_1 \ldots j_p}^{\mu_1 \ldots \mu_p} \Pi_{j_1 \ldots j_p}^{\lambda_1 \ldots \lambda_k}, \quad (47)$$

where $W_p$ is a hypersurface of constant $\tau$. Notice that since $B = B(\theta, x)$, the integrand above involves only superspace variables.

5. Applications: $p = 1, 2$

5.1. $D = 10, N = 1$ and the Green–Schwarz superstring

The case of the superstring is somewhat special, from the point of view of the extension algorithm of Section 3: the first additional generator to be introduced, $Z^m$, is a vector, as $X_\mu$. We shall keep it here separate and denote by $\varphi_\mu$ the associated parameter. Fixing $(a_\mu, a_0, a_1)$ = $(\frac{1}{2}, \frac{1}{2}, 1)$ in (18,21), we find for the FDA

$$d\Pi^\mu = 0, \quad d\Pi^\mu - \frac{i}{2} (\Gamma^\mu)_{\nu \rho} \Pi^\nu \Pi^\rho = (\Gamma^\mu)_{\nu \rho} \Pi^\nu \Pi^\rho, \quad (48)$$

where $\mu = 0, \ldots, 9$. Notice that $d(d\Pi_\mu) = 0$ is implied by (20) for $p = 1, \quad (\Gamma^\mu)_{\nu \rho} (\Gamma^\nu)_{\nu \rho} = 0, \quad \Pi^\mu_{(\psi)}$ in the above equation is the one obtained from the second of (18) for $p = 1$ – we have added a superscript to avoid any confusion with

---

11 Eqn. (46) for $j^{\lambda i}$ also follows from the standard expression for the current associated with an ‘internal’ symmetry of a Lagrangian $\mathcal{L}$. $j^{\lambda i} = \delta_{\xi} \varphi(\xi) \mathcal{L} = \delta_{\xi} \varphi(\xi).$ However, for the currents considered here the relevant part of $\mathcal{L}$ is just $\mathcal{L}_{WZ}$. Since $\mathcal{L}_{WZ}$ is obtained from a form on $\Sigma$, the above derivation allows us to exploit the geometry of $\Sigma$. The above expression for the current also makes clear that, within the canonical formalism, the integrated charge operators will reproduce the original symmetry algebra.

12 In Section 5.1 all spinors are Majorana–Weyl ($\theta^\alpha = (\theta^+, \theta^-)^\alpha$ etc.).
\( \Pi^\alpha \), since they have similar differentials; recall also that \( \Pi^a \) and \( \Pi^\alpha \) are unrelated. As mentioned in Section 3, the two terms in the r.h.s. of the last of (48) are individually closed and hence their relative normalization cannot be fixed by requiring \( d(d\Pi^a) = 0 \). We have nevertheless chosen the above symmetric normalization for convenience – the results that follow, and in particular (59) that involves cancellations, do not depend essentially on this choice.

The corresponding Lie algebra is given by
\[
\{ \mathcal{D}_a, \mathcal{D}_b \} = (C \Gamma^\mu)_{ab} X_\mu + (C \Gamma_\mu^a)_{ab} Z^\alpha. \quad [ \mathcal{D}_a, X_\mu ] = (C \Gamma_\mu^a)_{ab} Z^\beta.
\]
which reduces to the Green algebra [13] if one omits \( Z^a \). The associated group manifold (extended superspace) \( \mathcal{S} \) is parametrized by \((\theta^a, x^\mu, \varphi_\mu, \varphi_\alpha)\) via
\[
g(\theta^a, x^\mu, \varphi_\mu, \varphi_\alpha) = e^{\theta^a \mathcal{D}_a + x^\mu \mathcal{D}_a + \varphi_\mu \mathcal{D}_a + \varphi_\alpha \mathcal{D}_a + Z^a \mathcal{D}_a}.
\]
Making use of the Baker–Campbell–Hausdorff (BCH) formula, where, for the algebra (49), terms of order four and higher vanish, we find the \( \mathcal{S} \) group law
\[
\theta^{\alpha a} = \theta^{\alpha a} + \theta^a, \quad x^{\alpha a} = x^{\alpha a} + x^a - \frac{1}{2}(C \Gamma^\mu)_{ab} \theta^{\alpha a} \theta^{\beta b},
\]
\[
\varphi^{\alpha a} = \varphi^{\alpha a} + \frac{1}{2}(C \Gamma^\mu)_{ab} \theta^{\alpha a} \varphi^{\beta b} + \frac{1}{2}(C \Gamma^\mu)_{ab} \theta^{\alpha a} \theta^{\beta b} \varphi^a,
\]
\[
- \frac{1}{2}(C \Gamma^\mu)_{ab} \varphi_\alpha \varphi_\beta \gamma \theta^{\alpha a} \varphi_\gamma + \frac{1}{2}(C \Gamma^\mu)_{ab} \theta^{\alpha a} \theta^{\beta b} \varphi_\gamma.
\]
\[
\varphi^{\alpha a} = \varphi^{\alpha a} + \varphi_\alpha - \frac{1}{2}(C \Gamma^\mu)_{ab} \theta^{\alpha a} \theta^{\beta b}.
\]
The bilinear terms in the expression for \( \varphi^{\alpha a} \) are the ones that give rise to the fourth of the MC equations (48) – the trilinear terms are required by the associativity of the group law. Their sum gives the spinor valued two-cocycle \( \xi_\alpha \) associated with the central extension of \( \mathcal{S}(\theta^a, x^\mu, \varphi_\alpha) \) by \( \varphi_\alpha \).

One can now relate the LI one-forms to the coordinate differentials
\[
\Pi^\alpha = d\theta^\alpha,
\]
\[
\Pi^\mu = dx^\mu + \frac{1}{2}(C \Gamma^\mu)_{ab} \theta^{\alpha a} d\theta^a,
\]
\[
\Pi_\mu = d\varphi_\mu - \frac{1}{2}(C \Gamma^\mu)_{ab} \theta^{\alpha a} d\varphi_\alpha + \frac{1}{2}(C \Gamma^\mu)_{ab} x^a d\theta^b + \frac{1}{2}(C \Gamma^\mu)_{ab} \theta^a \varphi^b,
\]
\[
\Pi_\mu^{(\alpha)} = d\varphi_\mu + \frac{1}{2}(C \Gamma^\mu)_{ab} \theta^{\alpha a}.
\]
(see also Ref. [20] although, omitting \( \Pi_\mu^{(\alpha)} \), we disagree with the corresponding expressions there). One may check that the LI forms in (52) satisfy the FDA (48). From the group composition law, one can compute the LI vector fields dual to (52) satisfying (49)
\[
D_\alpha = \partial_\alpha + \frac{1}{2}(C \Gamma^\mu)_{ab} \theta^{\alpha a} \theta^{\beta b} + \frac{1}{2}(C \Gamma^\mu)_{ab} \theta^{\beta b} \theta^{\alpha a} - \frac{1}{2}(C \Gamma^\mu)_{ab} x^a \theta^{\beta b} - \frac{1}{2}(C \Gamma^\mu)_{ab} \theta^{\alpha a} \theta^{\beta b} \varphi^a,
\]
\[
X_\mu = \partial_\mu + \frac{1}{2}(C \Gamma^\mu)_{ab} \theta^{\beta b} \varphi^a,
\]
\[
Z^a = \partial^a + \frac{1}{2}(C \Gamma^\mu)_{ab} \theta^{\beta b} \varphi^a.
\]
\[
Z^a = \partial^a \left( \text{note } \partial^a \equiv \delta^a_i \partial_i \varphi_\mu, \quad \partial_\alpha \equiv \partial_i \partial_\mu \varphi_\alpha \right).
\]
Effecting a right group translation in (52) and reexpressing the result in terms of the \( \Pi^s \)’s, or computing the exponential in (31), one finds for \((T')^{-1}\)
\[
(T')^{-1} = \begin{pmatrix}
\delta^s_r & -(C\Gamma^r)_{\alpha\beta}\theta^\beta & \cdots & -(C\Gamma^r)_{\alpha\beta}\theta^s - (C\Gamma^r)_{\alpha\beta}\theta^s + (C\Gamma^r)_{\alpha\beta}\theta^s + (C\Gamma^r)_{\alpha\beta}\theta^s + (C\Gamma^r)_{\alpha\beta}\theta^s \\
0 & \delta^s_r & \cdots & 0 \delta^s_r \\
0 & 0 & \cdots & 0 \\
0 & 0 & \cdots & 0 \\
0 & 0 & \cdots & 0 \\
& & & 0
\end{pmatrix}
\]
(54)

(the matrix indices are \( y^\mu \) for the rows and \( a^\mu \) for the columns). When Eqs. (51) are linearized in the primed variables (viewed as the parameters of the transformation), they provide a realization of the algebra (49), acting on the coordinate (unprimed) variables. For our particular choice of parametrisation (50), this action is rendered non-linear by the last term in the expression for \( \varphi^\mu_\alpha \). This term can be eliminated by modifying the two-cocycle by a two-coboundary, the latter being generated by a suitable spinor-valued function \( \eta_\nu \) on \( \Sigma(\theta^\alpha, x^\mu, \varphi_\nu) \). Indeed, with \( \eta_\nu \equiv \frac{1}{2}(C\Gamma^\mu)_{\alpha\beta}x^\mu \theta^\beta + \frac{1}{2}(C\Gamma^\mu)_{\alpha\beta}\varphi_\mu \theta^\beta \) we find for the coboundary \( \xi^\nu_\alpha(\varphi', g) \equiv \eta_\nu(\varphi') - \eta_\nu(\varphi) - \eta_\nu(g) \), the expression
\[
\xi^\nu_\alpha = \frac{1}{2}(C\Gamma^\mu)_{\alpha\beta}x^\mu \theta^\beta + \frac{1}{2}(C\Gamma^\mu)_{\alpha\beta}\varphi_\mu \theta^\beta + \frac{1}{2}(C\Gamma^\mu)_{\alpha\beta}\varphi_\mu \theta^\beta - \frac{1}{2}(C\Gamma^\mu)_{\alpha\beta}\varphi_\mu \theta^\beta.
\]
(55)

The new cocycle \( \tilde{\xi}_\alpha = \xi_\alpha + \xi^\nu_\alpha \) modifies the last equation in (51) to read
\[
\tilde{\varphi}\;^\nu_\alpha = \tilde{\varphi}_\alpha + \tilde{\varphi}_\alpha + (C\Gamma^\mu)_{\alpha\beta}\left( \frac{1}{2}x^\mu \theta^\beta - \frac{1}{2}x^\mu \theta^\beta \right) + (C\Gamma^\mu)_{\alpha\beta}\left( \frac{1}{2}x^\mu \theta^\beta - \frac{1}{2}x^\mu \theta^\beta \right) + \frac{1}{2}(C\Gamma^\mu)_{\alpha\beta}\varphi_\mu \theta^\beta.
\]
(56)

which is linear in the unprimed variables although the definite symmetry properties under exchange of primed and unprimed variables are now lost. The terms in (56) linear in the primed coordinates agree (omitting \( \varphi_\nu \)) with the (first-order) results of Ref. [20], where the (equivalent) coordinate redefinition \( \varphi_\alpha \rightarrow \tilde{\varphi}_\alpha \equiv \varphi_\alpha + \eta_\nu \) is given. For the LI one-form associated with the new coordinate we find
\[
\Pi_{(\varphi)} = d\tilde{\varphi}_\alpha - \frac{1}{2}(C\Gamma^\mu)_{\alpha\beta}\theta^\beta dx^\mu - \frac{1}{2}(C\Gamma^\mu)_{\alpha\beta}\theta^\beta d\varphi_\alpha + \frac{1}{2}(C\Gamma^\mu)_{\alpha\beta}\varphi_\mu \theta^\beta + (C\Gamma^\mu)_{\alpha\beta}\varphi_\mu \theta^\beta + (C\Gamma^\mu)_{\alpha\beta}\varphi_\mu \theta^\beta d\theta^\beta.
\]
(57)

The manifestly invariant WZ term for the superstring action is given by
\[
S_{WZ} = \int_W \phi^* (\tilde{b}) = \int_W \phi^* (\Pi_{(\varphi)}^s \Pi^s + \frac{1}{2}\Pi_a \Pi^a).
\]
(58)

which differs from the one in [33] by the term in \( \Pi_{(\varphi)}^s \Pi^s \). It is immediately checked, using (48), (52), that \( \tilde{b} = db = (C\Gamma^\mu)_{\alpha\beta} \Pi^a \Pi^s \) and hence that \( \phi^* (\tilde{b}) \) and the standard WZ term \( \phi^* (b) \) are equivalent, differing only by an exact differential. Since the string tension \( T \) has dimensions \( [T] = ML^{-1} \) and \( [\Pi_{(\varphi)}^s] = L, [\Pi_a] = L^{-1/2} \), the products \( T\Pi_a, T\Pi_{(\varphi)}^s \Pi^s, T\Pi_{(\varphi)}^s \Pi^a, \) have the dimensions \( ML \) of an action.

To compute the conserved Noether currents, we start from (45) which gives the closed forms \( J^\mu \) on \( \Sigma \). With \( B^{-1} \) given by the lower right block of \((T')^{-1}\) (see (54), (26)) we get
\[
J^\mu = (B^{-1})^\mu_\alpha \Pi^a + \frac{1}{2}(B^{-1})^\mu_\alpha \Pi^a = \Pi^\mu - \frac{1}{2}(C\Gamma^\mu)_{\alpha\beta} \theta^\gamma d\theta^\beta = dx^\mu,
\]
\[
J^\mu = \frac{1}{2}(B^{-1})^\mu_\alpha \Pi^a = \frac{1}{2}d\theta^\alpha.
\]
(59)
which, after pulling back on the world-volume, gives for the charge \( Q^\alpha \) (see (47))

\[
Q^\alpha = \int_0^{2\pi} d\sigma \frac{\partial x^\mu}{\partial \sigma},
\]

(60)

\( Q^\alpha \) being zero because we assume that \( \theta \) is periodic in \( \sigma \). The integral (60) may lead to a non-zero result if the topology is non-trivial [12].

5.2. \( D = 11 \) and the case of the supermembrane

Our starting point is the FDA of Section 3 with \( p = 2 \). We fix the normalisation of the forms by setting \((a_1,a_0,a_1,a_2) = (\frac{1}{2},\frac{1}{2},1,-\frac{1}{2})\) so that the dual Lie algebra becomes

\[
\begin{align*}
\{D_a,D_b\} &= (CG^\alpha)_{a\beta}X^\mu + (CG^\alpha)_{a\beta}Z^\mu, \\
[X_\mu,D_a] &= -(CG^\alpha)_{a\beta}Z^\mu, \\
[X_\mu,X_\lambda] &= (CG^\alpha)_{a\beta}Z^{a\beta}, \\
[X_\mu,Z^\alpha] &= \frac{1}{2}\delta^\alpha_\mu (CG^\alpha)_{a\beta}Z^{a\beta}, \\
[D_a,Z^\alpha] &= (CG^\alpha)_{a\beta}Z^{a\beta}, \\
\{D_a,Z^\beta\} &= \left(\frac{1}{2}(CG^\alpha)_{\gamma\delta}^{\gamma\beta} + 2(CG^\alpha)_{\gamma\delta}^{\gamma\beta}\right)Z^\beta,
\end{align*}
\]

(61)

coinciding with that given in Ref. [16]. The associated extended superspace group manifold is parametrized by the coordinates \((\theta^\alpha, x^\mu, \phi_{\mu\alpha}, \Phi_{\mu\alpha}, \Phi_{\alpha\beta})\) via\(^{13}\)

\[
g = e^{\theta^a D_a+z^\alpha x^\mu+\phi_{\mu\alpha} Z^\mu+\Phi_{\mu\alpha} Z^{\mu\alpha}+\Phi_{\alpha\beta} Z^{\alpha\beta}},
\]

(62)

where \( \phi_{\mu\alpha}, \Phi_{\alpha\beta} \) are antisymmetric and symmetric, respectively, in their indices. Application (with the help of FORM) of the BCH formula, where now terms of order five and higher vanish, results in the following group law:

\[
\begin{align*}
\theta^{a\alpha'} &= \theta^{a\alpha'} + \theta^\alpha, \\
x^\mu' &= x^\mu + x^\mu - \frac{1}{2} \theta^{a\alpha'} \theta^{a\alpha}(CG^\alpha)_{a_1a_2}, \\
\phi_{\mu_1\mu_2} &= \phi_{\mu_1\mu_2} + \phi_{\mu_1\mu_2} - \frac{1}{2} \theta^{a\alpha'} \theta^{a\alpha}(CG^\alpha)_{a_1a_2} x^\mu, \\
\phi_{\mu_1\mu_2} &= \phi_{\mu_1\mu_2} \frac{1}{2} \theta^{a\alpha'} \theta^{a\alpha}(CG^\alpha)_{a_1a_2} x^\mu, \\
\phi_{\mu_1\mu_2} &= \phi_{\mu_1\mu_2} \frac{1}{2} \theta^{a\alpha'} \theta^{a\alpha}(CG^\alpha)_{a_1a_2} x^\mu, \\
\phi_{\alpha\beta} &= \phi_{\alpha\beta} + \frac{1}{4} (CG^\alpha)_{a_1a_2} x^\mu \phi_{\mu\alpha\beta} x^\mu, \\
\phi_{\alpha\beta} &= \phi_{\alpha\beta} + \frac{1}{4} (CG^\alpha)_{a_1a_2} x^\mu \phi_{\mu\alpha\beta} x^\mu, \\
\phi_{\alpha\beta} &= \phi_{\alpha\beta} + \frac{1}{4} (CG^\alpha)_{a_1a_2} x^\mu \phi_{\mu\alpha\beta} x^\mu, \\
\phi_{\alpha\beta} &= \phi_{\alpha\beta} + \frac{1}{4} (CG^\alpha)_{a_1a_2} x^\mu \phi_{\mu\alpha\beta} x^\mu.
\end{align*}
\]

\(^{13}\)We use a parametrization different from the one in Ref. [16].
\[ -\frac{1}{24} \theta^\alpha \theta^\beta \theta^\gamma \theta^\delta (C \Gamma^\mu)_{\alpha_1 \alpha_2} (C \Gamma^\nu)_{\alpha_3 \alpha_4} (C \Gamma^\rho)_{\alpha_5 \alpha_6} \]
\[ + \frac{1}{24} \theta^\alpha \theta^\beta \theta^\gamma \theta^\delta (C \Gamma^\mu)_{\alpha_1 \alpha_2} (C \Gamma^\nu)_{\alpha_3 \alpha_4} (C \Gamma^\rho)_{\alpha_5 \alpha_6} \]
\[ Z^{a_1a_2} = \partial^{a_1a_2} + \frac{1}{8} \theta^{a_2} (C \Gamma^{\mu})_{a_3a_4} \partial^{a_3a_4} + \theta^{a_2} (C \Gamma^{\mu})_{a_3a_4} \partial^{a_3a_4}, \]

\[ Z^a - \partial^a, \]  

(antisymmetrization with unit weight in \( \mu_1, \mu_2 \) is understood in the r.h.s. of the expression for \( Z^{a_1a_2} \).) The manifestly invariant WZ term on the extended superspace \( \Sigma \) is given by \[ \tilde{b} = \frac{1}{2} \Pi_{\mu_2} \Pi^\mu - \frac{1}{2} \Pi_{\mu_3} \Pi_{\mu_4} - \frac{1}{2 \pi} \Pi_{\alpha_2} \Pi^\alpha \]

([\( \tilde{b} \) = \( L \), \( \Pi \) = \( M \text{L} \)]. It depends on the additional \( \varphi \) variables through total differentials since \( \tilde{d} \Pi = \tilde{d} \Pi = \hbar = (C \Gamma^{\mu}_{\gamma})_{\alpha \beta} \Pi^\mu \Pi^{\alpha \beta} \).

The computation of the full \( T \) matrix for the supermembrane is rather tedious. For the Noether currents though (corresponding to the new variables) we only need \( B^{-1} \).

Reading off the relevant structure constants from (61), we find

\[ \rho^{(f)}(D_a) = \begin{pmatrix} 0 & 0 & 0 \\ 0 & \frac{1}{4} (C \Gamma^{\alpha})_{\beta_1 \gamma_2} \delta^{a_1}_{\alpha_1} + 2(C \Gamma^{\alpha})_{\beta_1 \gamma_2} \delta^{a_1}_{\alpha_2} & 0 \\ 0 & 0 & 0 \end{pmatrix}, \]

\[ \rho^{(f)}(X_a) = \begin{pmatrix} \frac{1}{2} \delta^a_{\beta_1 \gamma_1} (C \Gamma^{\alpha})_{\beta_2 \gamma_2} & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}. \]  

Using these in the exponential in (32) we get for \( B^{-1} \)

\[ B^{-1} = \begin{pmatrix} \delta^{\mu_1 \nu_1}_{\alpha_1 \beta_1} - \theta^a (C \Gamma^{\mu})_{a_3a_4} \delta^{r_1}_{s_1} & -\frac{1}{2} \theta^a (C \Gamma^{\mu})_{a_3a_4} \delta^{r_1}_{s_1} + \theta^a \delta_{\beta_1 \gamma_1} + \theta^a \delta_{\beta_2 \gamma_2} \\ 0 & \delta^{\nu_1}_{s_2} & \delta^{\nu_1}_{s_2} \\ 0 & 0 & 0 \end{pmatrix}. \]

The above locally exact expressions result from rather non-trivial cancellations. The currents are obtained by pulling back to \( W \) the forms (76). For periodic \( \theta \)'s the charges \( Q^{a_1a_2}, Q^{\beta_1 \gamma_1} \) (but not \( Q^{\mu_1 \nu_1} \) for a non-trivial two-cycle \([12]\)) turn out to be zero. Thus, this case provides a realization of the algebra (61) where only the \( Q^{\mu_1 \nu_1} \) term is non-zero.
6. The case of D-branes

Let us consider first a bosonic background for which all forms of the $R \otimes R$ sector and the dilaton vanish so that the two-form $\mathcal{F} = F - B$, where $F = dA$ and $B$ is the NS $\otimes$ NS two-form, reduces to $F$; $A$ is the Born-Infeld one-form on the world-volume $A(\xi) = A(\xi) d\xi^i$. Then the action of the $Dp$-brane reduces to

$$I = \int d^{p+1} \xi \left[ - \det( \partial_i x^\mu, x^i + F_{ij}) \right].$$  \hspace{1cm} (77)

Let us look for a manifestly supersymmetric generalisation of this action on a suitable extension of flat superspace we shall consider here only $D = 10$, IIA D-branes. For the ordinary $p$-branes the supersymmetrisation is achieved by substituting first $P_m$ for $i_m$ and then by adding a WZ term $db = h$, with $h$ characterised by being a non-trivial CE cohomology $p$-2-cocycle on superspace $\Sigma$. It was shown in the previous sections how to make these WZ terms manifestly invariant. We shall extend this to the $Dp$-branes case by showing first that the WZ terms may be characterised and classified by CE-cocycles as well, and then by finding manifestly supersymmetric potentials $b$ on the superspaces $\Sigma$ which are obtained by the techniques of Section 3 or by dimensional reduction from these. We shall restrict ourselves here to the $D2$-brane case, and hence to its associated $\Sigma$ parametrised by $(\theta^a, x^\mu, \varphi_{\mu\alpha}, \varphi_{\mu\beta}, \varphi_{\alpha\beta}^\mu, \varphi_{\alpha\beta})$.

6.1. CE-cocycle classification of D-branes

The new feature in the $Dp$-brane case is the field $A(\xi)$ directly defined on the world-volume. The one-form $A$ transforms under supersymmetry in such a way that $\mathcal{F} = dA - B$ is invariant, where $B$ is a two-form on superspace such that

$$dB = - \Pi^a \left( C^a_{\mu\nu} \right)_{\alpha\beta} \Pi^\alpha \Pi^\beta.$$  \hspace{1cm} (78)

Let us now consider $A$ as an abstract form. In our approach, the possible WZ terms will be some non-trivial $(p + 2)$-cocycles of the cohomology of a certain FDA (here, of IIA type). This FDA is generated by the supersymmetric invariant $\Pi^a, \Pi^\alpha$ and $\mathcal{F}$ and defined by the structure relations

$$d \Pi^a = 0, \quad d \Pi^\alpha = \frac{1}{2} \left( C^a_{\mu\nu} \right)_{\alpha\beta} \Pi^a \Pi^\beta, \quad d \mathcal{F} = \Pi^a \left( C^a_{\mu\nu} \Gamma_{\alpha\beta} \right)_{\alpha\beta} \Pi^\alpha \Pi^\beta.$$  \hspace{1cm} (79)

Note that $dd = 0$ because the identity $(C^a_{\mu\nu} \Gamma_{\alpha\beta})_{\alpha\beta} = 0$ is valid in $D = 10$. The non-trivial $(p + 2)$-cocycles are given by closed $(p + 2)$-forms $h$ constructed from $\Pi^a, \Pi^\alpha, \mathcal{F}$ that cannot be written as the differential of a $(p + 1)$-form constructed from them, and with the same dimensions as the kinetic Lagrangian, i.e. $[h] = L^{p+1}$. This second requirement is necessary to avoid introducing dimensionful constants in the action other than the tension, $[T] = ML^{-p}$.

Since $\mathcal{F}$ is a two-form, $h$ can be expanded in powers of $\mathcal{F}$ as

$$h = \sum_{n=0}^{\frac{p+2}{2}} \frac{1}{n!} h^{(p+2-2n)}(\Pi^a, \Pi^\alpha) \mathcal{F}^n.$$  \hspace{1cm} (80)
where $h^{(k)}$ is a form of order $k = p + 2 - 2n$ and, since $D = 10$, $p \leq 8$ excluding the degenerate case $p = 1 = 10$. Moreover, since $[h^{(p + 2 - 2n)}] = L^{p + 1 - 2n}$, the $k$-forms $h^{(k)}$, $[h^{(k)}] = L^{k-1}$, must be

$$h^{(k)} = a^{(i)} \Pi^{\mu_1} \cdots \Pi^{\mu_k-1} (C \Gamma_{\mu_1 \cdots \mu_{k-2}})_{\alpha \beta} \Pi^\alpha \Pi^\beta, \quad k = 2, \ldots, p + 2, \quad (81)$$

where $\Gamma = 1$ or $\Gamma_{11}$ so that $(C \Gamma_{\mu_1 \cdots \mu_{k-2}})_{\alpha \beta}$ is symmetric (i.e., $k - 2 = 1,2,5,6,9,10$ for $1$ and $0,1,4,5,8,9$ for $\Gamma_{11}$). Since

$$d \mu = \sum_{n=0}^{\frac{p+2}{2}} \frac{1}{n!} dh^{(p + 2 - 2n)} \mathcal{F}^n$$

+ $\sum_{n=1}^{\frac{p+2}{2}} \frac{1}{(n-1)!} (-1)^n h^{(p + 2 - 2n)} (C \Gamma_{\mu_1 \Gamma_{11}})_{\alpha \beta} \Pi^\alpha \Pi^\beta \mathcal{F}^{n-1}, \quad (82)$

the required closure of $h$ is equivalent to the following set of equations:

$$d h^{(p - 2 \lfloor p/2 \rfloor)} = 0, \quad \text{for } n = \left\lfloor \frac{p + 2}{2} \right\rfloor$$

$$d h^{(p + 2 - 2n)} + (-1)^n h^{(p - 2n)} \Pi^\alpha \Pi^\beta (C \Gamma_{\mu_1 \Gamma_{11}})_{\alpha \beta} = 0, \quad \text{for } n = \left\lfloor \frac{p}{2} \right\rfloor \ldots 0. \quad (83)$$

At this point it is convenient to examine separately the $p$ odd and $p$ even cases.

(a) $p$ even

The first equation in (83) gives $d h^{(0)} = 0$. This means $h^{(0)} = 0$ because $h^{(0)} \neq 0$ would imply by (80) having an additional dimensionful constant, $[h^{(0)}] = L^{-1} ([\mathcal{F}] = L^2)$. For $n = \frac{1}{2}$ the second of (83) gives $d h^{(2)} = 0$. Inserting $h^{(2)}$ from Eq. (81), we obtain an identity, so $a^{(2)}$ is arbitrary.\footnote{We note in passing that in the heterotic case, for which $N = 1$ ($\Pi^a$ is MW), $d h^{(2)} = 0$ because $(C \Gamma_{11})_{\alpha \beta} \Pi^\alpha \Pi^\beta = C_{\alpha \beta} \Pi^\alpha \Pi^\beta = 0$ since $(\Gamma_{11})_{\alpha \beta} \Pi^\alpha \Pi^\beta = \Pi^\alpha \Pi^\beta$. So the chain of equations that follows does not appear and there are no non-trivial WZ terms. This shows, as expected, that there are no D-branes in the heterotic case.}

The remaining equations (for $n = \frac{1}{2}, \ldots$) are equivalent, by factoring out products of forms $\Pi^a$ and $\Pi^a$, to

$$2 d(6) (C \Gamma_{\mu_1})_{\alpha \beta} (C \Gamma_{\mu_2 \Gamma_{11}})_{\alpha \beta} = 0,$$

$$3 d(8) (C \Gamma_{\mu_2})_{\alpha \beta} (C \Gamma_{\mu_3 \Gamma_{11}})_{\alpha \beta} = 0,$$

$$4 d(10) (C \Gamma_{\mu_3})_{\alpha \beta} (C \Gamma_{\mu_4 \Gamma_{11}})_{\alpha \beta} = 0. \quad (84)$$

Note that the number of identities from (84) that are necessary to show that $h$ is closed depends on the values of $p$ since $2 \leq k \leq p + 2$, $k$ even. Specifically, for the D2-brane
only the first identity is used, for the D4-brane the first two identities are relevant and the first three (four) identities are required for the existence of the D6-(D8-)branes.

Eqs. (84) have to be identically satisfied for certain values of the a’s to be determined. To find them, one may multiply the equations by \((\Gamma^\nu C^{-1})^{\beta\delta}\) (although the resulting system is not equivalent to the original one). This procedure gives some equalities between gamma matrices that are only satisfied if \(d^{(3)} = -d^{(2)}, \quad d^{(3)} = -6d^{(6)}, \quad d^{(5)} = -15d^{(8)}\) and \(d^{(6)} = -28d^{(10)}\). These values are the solution of Eqs. (84) and determine closed forms \(h\) by (80). (81) provided that the following identities are satisfied:

\[
\begin{align*}
(C\Gamma^{\mu\nu})_{a\beta}((C\Gamma_{a\beta,\mu\nu})_{\gamma\delta} + (C\Gamma_{\mu\nu})_{a\beta}((C\Gamma_{\mu\nu})_{\gamma\delta})_{\delta\gamma} & = 0, \\
(C\Gamma^{\mu\nu})_{a\beta}((C\Gamma_{\mu\nu})_{a\beta}((C\Gamma_{\mu\nu})_{\gamma\delta})_{\delta\gamma} + 5(C\Gamma_{\mu\nu})_{a\beta}((C\Gamma_{\mu\nu})_{\gamma\delta})_{\delta\gamma} & = 0, \\
(C\Gamma^{\mu\nu})_{a\beta}((C\Gamma_{\mu\nu})_{a\beta}((C\Gamma_{\mu\nu})_{\gamma\delta})_{\delta\gamma} + 7(C\Gamma_{\mu\nu})_{a\beta}((C\Gamma_{\mu\nu})_{\gamma\delta})_{\delta\gamma} & = 0,
\end{align*}
\]

(85)
as is indeed the case (see Appendix B). Therefore we have shown that, for \(p\) even, there exist closed \((p + 2)\)-forms \(h\) with the required dimensions for all even values of \(p, p \leq 8\).

To prove that the \(h\)’s obtained from Eq. (81) for the appropriate values of \(a^{(k)}\) are not CE-trivial, it is sufficient to note that if there were a potential form \(b(\Pi^\mu,\Pi^\nu,\mathcal{F})\), \(db = h\), then this form would be a Lorentz-invariant \((p + 1)\)-form with physical dimensions \(L^{p+1}\), which does not exist for \(p + 1 < 10\) since \(p\) is even.

(b) \(p\) odd

In this case, the first equation in (83) gives \(dh^{(1)} = 0\). Again, this means \(h^{(1)} = 0\) because obviously there are no Lorentz-scalar one-forms that can be constructed from \(\Pi^\mu, \Pi^\nu\) and \(\mathcal{F}\). On the other hand, \(k\) in \(h^{(k)}\) has now the range \(3 \leq k \leq p + 2, k\) odd. Of these \(h^{(k)}\), those corresponding to \(k = 5\) and \(k = 9\) vanish independently of the type of the matrix \(\Gamma\) (see Table 1). This leaves us with \(h^{(3)}\) and \(h^{(7)}\) and the second of (83) leads to

\[
\begin{align*}
d^{(3)}(C\Gamma^{\mu\nu})_{a\beta}((C\Gamma_{\mu\nu})_{\gamma\delta})_{\delta\gamma} & = 0, & d^{(3)}(C\Gamma_{\mu\nu})_{a\beta}(C\Gamma_{\mu\nu})_{\gamma\delta})_{\delta\gamma} & = 0, \\
d^{(3)}(C\Gamma^{\mu\nu})_{a\beta}((C\Gamma_{\mu\nu})_{\gamma\delta})_{\delta\gamma} & = 0, & d^{(3)}(C\Gamma_{\mu\nu})_{a\beta}((C\Gamma_{\mu\nu})_{\gamma\delta})_{\delta\gamma} & = 0.
\end{align*}
\]

(86)

In the \(d^{(5)}\) equations, \(\Gamma\) has to be \(\Gamma_{11}\) (the other possibility, \(132\), may be shown to be inconsistent by multiplying the second expression by \((\Gamma^\nu C^{-1})^{\beta\delta}\)). Multiplying the fourth equation by \((\Gamma^\nu C^{-1})^{\beta\delta}\) shows that \(d^{(7)} = 0\) for both \(\Gamma = 1, \Gamma_{11}\). Thus we have shown that the only candidate for a WZ term in the odd \(p\) case is obtained from \(h^{(3)}\), i.e. from

\[
h = \Pi^\mu(C\Gamma_{\mu\nu})_{a\beta} \Pi^\nu \Pi^\beta \mathcal{F} \frac{p - 1}{2}, \quad p \geq 1.
\]

(87)
But then \( h = d(\frac{1}{p+1/p})^2 \) by (79), and hence is a trivial CE cocycle. Therefore in the \( D = 10 \), IIA theory there are no non-trivial WZ terms for the D-branes with \( p \) odd. The other values for \( p \) found in our discussion are precisely those for which D-branes of type IIA are known to exist. Thus the IIA D-branes are, as the scalar \( p \)-branes \([2] \), characterized by non-trivial CE cocycles.

6.2. D-branes defined on extended superspace

As we saw, one reason for considering superspace extensions associated with extended objects is that it is possible to find on \( \sum \) manifestly invariant WZ terms since then \( h \) may be expressed as the differential of a LI form \( \tilde{h} \). We shall now show that this is also possible for the D2-brane. The starting point is now the FDA given in Eq. (17) with the generators with more than two vector indices absent, plus the equation for \( d\mathcal{F} \), i.e.

\[
\begin{align*}
&d\Pi^\alpha = 0, \\
&d\Pi = \frac{1}{2} (C\Gamma_{\alpha\beta})_{\mu\nu} \Pi^\alpha \Pi^\beta, \\
&d\Pi^\mu = \frac{1}{2} (C\Gamma_{\mu\nu})_{\alpha\beta} \Pi^\alpha \Pi^\beta,
\end{align*}
\]

(88)

The reason one should start from (88) is that the dual of the algebra defined by the first five equations is the one obtained when one computes the algebra of the Noether charges associated with the supertranslations in the case of the type IIA D2-brane (see Ref. [38]).

The next step, as was done in Section 3, is extending this algebra with the generators obtained by replacing vector indices by spinorial ones. In the case of the D2-brane this is not difficult to do because, apart from the equation for \( d\mathcal{F} \), the free differential algebra one starts with is actually the-dimensional reduction of the eleven-dimensional one

\[
\begin{align*}
&d\Pi^\alpha = \frac{1}{2} (C\Gamma_{\alpha\beta})_{\mu\nu} \Pi^\alpha \Pi^\beta, \\
&d\Pi = \frac{1}{2} (C\Gamma_{\mu\nu})_{\alpha\beta} \Pi^\alpha \Pi^\beta,
\end{align*}
\]

(89)

in which one sets \( \Pi^\beta \equiv (\Pi^\mu, \Pi^{10} = \Pi) \). \( \Pi_{\alpha\beta} \equiv (\Pi_{\alpha\nu}, \Pi_{\mu10} = \Pi_{\mu}^{(c)}) \). Since this \( D = 11 \) algebra has already been extended recursively in Section 3 by the new one-forms \( \Pi_{\mu\nu} \) and \( \Pi_{\alpha\beta} \), the extended algebra in \( D = 10 \) is simply its-dimensional reduction, for which \( \Pi_{\alpha\beta} \equiv (\Pi_{\alpha\beta}, \Pi_{\alpha}^{(c)}) \). The result is given by Eqs. (88) plus

\[
\begin{align*}
&d\Pi_{\mu\nu} = (C\Gamma_{\mu\nu})_{\alpha\beta} \Pi^\alpha \Pi^\beta + (C\Gamma_{\mu11} \Gamma_{\nu})_{\alpha\beta} \Pi^\alpha \Pi^\beta + (C\Gamma_{\nu})_{\alpha\beta} \Pi^\alpha \Pi^\beta \\
&\quad - (C\Gamma_{\nu11} \Gamma_{\nu})_{\alpha\beta} \Pi^\alpha \Pi^\beta, \\
&d\Pi_{\alpha}^{(c)} = (C\Gamma_{\alpha11} \Gamma_{\nu})_{\alpha\beta} \Pi^\alpha \Pi^\beta + (C\Gamma_{\nu})_{\alpha\beta} \Pi_{\alpha}^{(c)} \Pi^\beta, \\
&d\Pi_{\mu\nu} = -\frac{1}{2} (C\Gamma_{\mu\nu})_{\alpha\beta} \Pi^\alpha \Pi^\beta - (C\Gamma_{\mu11} \Gamma_{\nu})_{\alpha\beta} \Pi^\alpha \Pi^\beta - \frac{1}{2} (C\Gamma_{\nu})_{\alpha\beta} \Pi_{\nu}^{(c)} \Pi^\beta \\
&\quad + \frac{1}{2} (C\Gamma_{\mu11} \Gamma_{\nu})_{\alpha\beta} \Pi_{\nu}^{(c)} \Pi^\beta + \frac{1}{2} (C\Gamma_{\nu})_{\alpha\beta} \Pi_{\mu\nu} \Pi^\beta \\
&\quad + \frac{1}{4} (C\Gamma_{\mu11} \Gamma_{\nu})_{\alpha\beta} \Pi_{\mu\nu} \Pi^\beta + 2(C\Gamma_{\nu})_{\alpha\beta} \Pi_{\mu\nu} \Pi^\beta + 2(C\Gamma_{\nu11} \Gamma_{\nu})_{\alpha\beta} \Pi_{\nu}^{(c)} \Pi^\beta.
\end{align*}
\]

(90)
which, apart from the \( d\mathcal{F} \) equation, corresponds to the-dimensional reduction of (61) (with \( Z^\mu = 2 Z^{10}_\mu \))

\[
\{ D_\alpha, D_\beta \} = (C \Gamma^\mu)_{\alpha \beta} X^\mu + (C \Gamma_{\mu \nu})_{\alpha \beta} Z^{\mu \nu} + (C \Gamma_{\mu 11})_{\alpha \beta} Z^\mu + (C \Gamma_{\mu 11})_{\alpha \beta} Z^\mu ,
\]

\[
\{ X_\mu, D_\alpha \} = -(C \Gamma^{\mu \nu})_{\alpha \beta} Z^{\nu \beta} - (C \Gamma_{\mu 11})_{\alpha \beta} Z^\mu ,
\]

\[
\{ Z, D_\alpha \} = (C \Gamma_{11 \mu})_{\alpha \beta} Z_{\beta \mu} ,
\]

\[
\{ X_\mu, X_\nu \} = (C \Gamma^{\mu \nu})_{\alpha \beta} Z^{\alpha \beta} ,
\]

\[
\{ Z, X_\mu \} = (C \Gamma_{11 \mu})_{\alpha \beta} Z^{\alpha \beta} ,
\]

\[
\{ X_\mu, Z^\nu \} = \frac{1}{2} \delta_\mu^\nu (C \Gamma_{\gamma 1})_{\alpha \beta} Z^{\alpha \beta} ,
\]

\[
\{ X_\mu, Z^\nu \} = \frac{1}{2} \delta_\mu^\nu (C \Gamma_{11})_{\alpha \beta} Z^{\alpha \beta} ,
\]

\[
\{ Z, Z^\mu \} = -\frac{1}{2} (C \Gamma^{\mu \nu})_{\alpha \beta} Z^{\alpha \beta} ,
\]

\[
\{ D_\alpha, Z^\nu \} = (C \Gamma^{\mu \nu})_{\alpha \beta} Z_{\beta \mu} ,
\]

\[
\{ D_\alpha, Z^\nu \} = -(C \Gamma_{11})_{\alpha \beta} Z_{\beta \mu} + (C \Gamma^\mu)_{\alpha \beta} Z^\mu ,
\]

\[
\{ D_\alpha, Z^\nu \} = \left( \frac{1}{2} (C \Gamma_{\nu})_{\gamma \delta} \delta_\alpha^\gamma + 2 (C \Gamma_{\nu})_{\gamma \delta} \delta_\beta^\gamma \right) Z^\gamma ,
\]

\[
\{ D_\alpha, Z^\nu \} = \left( \frac{1}{2} (C \Gamma_{11})_{\gamma \delta} \delta_\alpha^\gamma + 2 (C \Gamma_{11})_{\gamma \delta} \delta_\beta^\gamma \right) Z^\gamma .
\]  

\[(91)\]

We can now show, using the new forms in (90), that it is possible to find an invariant WZ term \( h = d\tilde{b} \), on the extended superspace. In our case \( h \) is given by (Eqs. 80), (81); \( k = 2,4 \)

\[
h = (C \Gamma_{\mu \nu})_{\alpha \beta} \Pi^\alpha \Pi^\beta \Pi^\alpha \Pi^\beta - (C \Gamma_{11})_{\alpha \beta} \Pi^\alpha \Pi^\beta .
\]  

\[(92)\]

Again, it is possible to expand \( \tilde{b} \) as \( \tilde{b} = b^{(3)} + b^{(1)} \mathcal{F} \). Using this expression in \( h = \tilde{b} \), and identifying the result with \( h \), yields \( db^{(1)} = -2 \Pi \), from which follows that \( b^{(1)} = -2 \Pi \). Similarly,

\[
\begin{align*}
\int b^{(3)} &= -2 (C \Gamma_{\mu \nu})_{\alpha \beta} \Pi^\alpha \Pi^\beta \\
&= (C \Gamma_{\mu \nu})_{\alpha \beta} \Pi^\alpha \Pi^\beta \Pi^\alpha \Pi^\beta
\end{align*}
\]  

\[(93)\]

where in the last equality we have rewritten the expression using the eleven-dimensional notation. This has the advantage that the expression for \( b^{(3)} \) in \( D = 11 \) was given in (73),

\[
b^{(3)} = \frac{1}{3} \Pi_{\alpha \beta} \Pi^2 \Pi^\alpha \Pi^\beta - \frac{2}{15} \Pi_{\alpha \beta} \Pi^{11} \Pi^\alpha \Pi^\beta - \frac{1}{3} \Pi_{\alpha \alpha} \Pi^2 \Pi^\alpha .
\]  

\[(94)\]

Reducing (94) to \( D = 10 \) and adding \( b^{(1)} \mathcal{F} = -2 \Pi \mathcal{F} \) we find the invariant WZ term,

\[
b = \frac{1}{3} \Pi_{\mu \nu} \Pi^\mu \Pi^\nu + \frac{1}{2} \Pi_{\mu \nu} \Pi^\mu \Pi^\nu - \frac{1}{15} \Pi_{\alpha \beta} \Pi^{11} \Pi^\alpha \Pi^\beta - \frac{1}{3} \Pi_{\alpha \alpha} \Pi^2 \Pi^\alpha - \frac{1}{3} \Pi_{\alpha} \Pi^2 \Pi^\alpha
\]  

\[\mathcal{F} = -2 \Pi \mathcal{F} .
\]  

\[(95)\]

This shows that on the extended superspace corresponding to Eqs. (88) and (90), the WZ term of the type IIA D2-brane can be made invariant, as was the case for the ordinary \( p \)-branes. We expect that this result holds for the other values of \( p \).
In contrast with the case of ordinary $p$-branes, the extended free differential algebra is not the dual of a Lie algebra because of the equation for the two-form $d\mathcal{F}$. However, it is easy to check that

$$d\left(\frac{1}{2}\Pi^a\Pi^a\right) - \Pi^a\Pi^a = (C\Gamma_\mu\Gamma_{11})_{ab}\Pi^a\Pi^b$$

so that, on the extended superspace, we may set

$$\mathcal{F} = \frac{1}{2}\Pi^a\Pi^a - \Pi^a\Pi^a,$$  \hspace{1cm} (97)

in accordance with (88), (90). This is not a surprising fact since from (88) we see that $d\mathcal{F}$ is equal to the $h$ corresponding to the WZ term of the type IIA superstring on a flat background. So it has to be possible to write it as the differential of an invariant form $\mathcal{B} = b(\Pi^\mu, \Pi^a, \Pi^a\Pi^a)$ on the fully extended superspace $\mathcal{S}$ of the IIA superstring. Since $\mathcal{F} = d\mathcal{A} - \mathcal{B}$ and $\mathcal{B}$ is defined on $\mathcal{S}$, $d\mathcal{A}$ may be written on $\mathcal{S}$. Making use of its LI forms, i.e. of

$$\Pi^a = d\theta^a,$$

$$\Pi^\mu = dx^\mu + \frac{1}{2}(C\Gamma^\mu)_{ab}\theta^a d\theta^b,$$

$$\Pi^a\Pi^a = d\phi + \frac{1}{2}(C\Gamma^a)(C\Gamma_a)_{ab}\theta^a d\theta^b,$$

$$\Pi^\mu\Pi^\mu = d\phi - (C\Gamma^\mu)(C\Gamma^\mu)_{ab}\theta^a d\theta^b - \frac{1}{16}(C\Gamma^\mu)(C\Gamma^a)(C\Gamma^a)_{ab}\theta^a d\theta^b,$$

it is easy to identify $\mathcal{A}$ as the one-form on $\mathcal{S}$

$$\mathcal{A} = \phi dx^a + \frac{1}{2}\phi_a d\theta^a.$$  \hspace{1cm} (99)

In this way, the customary Born-Infeld world-volume field $\mathcal{A}(\xi)$ becomes here $\phi\psi^\ast(\mathcal{A})$, with $\mathcal{A}$ on $\mathcal{S}$ given by (99), and its existence may be looked at as a consequence of extended supersymmetry.

The previous discussion shows that it is natural to rewrite the action of the D-branes on a flat background by using only objects that are initially defined on the appropriately extended superspace. We show now that the Euler–Lagrange (EL) equations are still the same (provided a rather natural condition is met) and that the gauge transformations of $\mathcal{A}$ can be reinterpreted in the new language. So at this point it seems that the geometric difference between the ordinary $p$-branes and the $Dp$-branes is that while the action of the former may be defined from forms on ordinary superspace $\Sigma$, the action of the latter requires the extended superspace of the IIA superstring if one wishes to avoid objects that only have a meaning on the world-volume. In the IIA superstring case the extended superspace was also considered, but the new variables appeared only in the WZ term and as total derivatives (Section 5.1) and thus had trivial EL equations. In the D-brane case, in contrast, these variables have non-trivial EL equations.

Let us now see how the EL equations change by making the substitution $A = \phi dx^a + \frac{1}{2}\phi_a d\theta^a$. Let $I[x^\mu, \theta^a, A]$ be the action before making the substitution, where $A$ are the coordinates of the form $A (A = A, d\xi)$. The EL equations are

$$\frac{\delta I}{\delta x^\mu} = 0, \hspace{1cm} \frac{\delta I}{\delta \theta^a} = 0, \hspace{1cm} \frac{\delta I}{\delta A} = 0.$$  \hspace{1cm} (100)
When the substitution is made, there are new terms in the equations, and they read
\[
\int d\xi' r A_j(\xi^{'}) \delta A_j(\xi^{'}) + \frac{\delta A_j}{\delta A_j} d x^\mu = 0, \\
\int d\xi' r A_j(\xi^{'}) \delta x^\mu(\xi^{'}) + \frac{\delta A_j}{\delta A_j} d x^\mu = 0
\]
where the additional contributions come from the partial functional derivative terms. If \( \frac{\delta I}{\delta A_j} d x^\mu \) and \( \frac{\delta I}{\delta A_j} d \theta^\alpha \) were zero without \( \frac{\delta I}{\delta A_j} d x^\mu \) being zero, this would imply the collapse of one world-volume dimension. Thus, we must have \( \frac{\delta I}{\delta A_j} d x^\mu = 0 \) which in the first equation of each set in (101) implies Eqs. (100). Hence both actions are equivalent. In fact, it may be shown that there is an additional gauge freedom which accounts for the difference of degrees of freedom between \( A(\xi) \) and \( A_j(\xi) \), but we shall not discuss this here. This seems to indicate that, when the action on \( W \) is obtained from entities on \( \Sigma \), there is an additional gauge freedom which in our formulation plays a rôle complementing that of \( \kappa \)-symmetry.

Finally, the \( U(1) \) gauge field \( A_j(\xi) \) on \( W \) has a gauge transformation \( \delta A_j(\xi) = \partial_j A(\xi) \). The question now is what is the gauge transformation of the component fields if one writes \( A_j d \xi^i \) as \( \phi^*(A) \). In other words, for a given \( A(\xi) \), there should be a transformation of \( \phi_\mu \) and \( \phi_\sigma \) in (99) reproducing \( \partial_j A(\xi) \). This may be obtained by means of a superfield \( \lambda \) such that \( \phi^*(A(\mu, \theta^\alpha)) = A(\xi) \). Then, if under a gauge transformation one defines \( \delta \lambda = \partial_\mu \lambda \) and \( \delta \phi_\sigma = 2 \partial_\sigma \lambda \), \( \phi^*(A) \) behaves as expected since then \( \delta \phi^* \left[ \phi_\sigma d x^\mu + \frac{1}{2} \phi_\sigma d \theta^\alpha \right] = \partial_\sigma A \). The fact that when the supersymmetry transformations of a field close only modulus a gauge transformation one obtains an extension of a FDA is not restricted to \( Dp \)-branes. In fact, one may achieve manifest invariance by introducing an electromagnetic potential on the world-sheet in the Green–Schwarz superstring action, in which case the string tension is the circulation of the potential around the string (49) (see also Ref. [49]) and a similar result applies to the other scalar \( p \)-branes [50]. Clearly, the world-volume fields introduced there could be defined on our appropriate extended superspaces as well. As for the IIB \( Dp \)-brane, an analysis similar to that in this section for the IIA case would classify them by first showing that WZ terms exist for odd \( p \). In a second stage, the world-volume gauge field \( A \) may be expressed as the pull-back of a IIB superspace one-form. In fact, this last point for the \( A \) in the \( p = 1 \) IIB D-string case has been discussed very recently in [22] by introducing an appropriate extended group manifold. We may conclude, then, that the different world-volume fields may be expressed in terms of forms defined on suitably extended superspaces.

7. Noether charges and D-brane actions

It follows from the discussion of Section 6 that the world-volume field \( A(\xi) \) that appears in the D2-brane action may be written on the superstring extended superspace

\[\text{We thank P. Townsend for discussions on this point.}\]
parametrized by \((x^\mu, \theta^\alpha, \varphi_\mu, \varphi_\alpha)\). On the other hand, the D2-WZ term, which is quasi-invariant in these coordinates, can be made strictly invariant by further extending the previous superspace to \(\hat{\Sigma} = (\theta^\alpha, x^\mu, \varphi_\mu, \varphi_\alpha, \varphi_{\mu\nu}, \varphi_{\alpha\beta}, \varphi)\). In this way, the whole action is invariant.

If one now computes the canonical commutators (or Poisson brackets) of the charges corresponding to the symmetries of the action, the resulting algebra is exactly the RI version of the Lie algebra dual to 88 (removing its last line plus 90), given in (91). The RI generator algebra \(\{Q, Q\}\) is the same as (91) with an additional minus sign on the r.h.s. Let us concentrate on the \(\{Q_\alpha, Q_\beta\}\) commutator,

\[
\{Q_\alpha, Q_\beta\} = (C \Gamma^\mu)_{\alpha\beta} P_\mu + (C \Gamma_\mu \Gamma_{11})_{\alpha\beta} \hat{Z}^\mu + (C \Gamma_{\mu\nu})_{\alpha\beta} \hat{Z}^{\mu\nu} + (C \Gamma_{11})_{\alpha\beta} \hat{Z}^{11}
\]

(102)

(this has been a redefinition of the generators so that \(\{Q, Q\} = + C \Gamma_\mu P_\mu\) etc.). Let us assume that we had written the action, as is customary, in terms of \((x^\mu, \theta^\alpha, A)\) alone, with \(A = A(\xi)\) directly defined on \(W\). In this case, the \(C \Gamma_\mu\) and \(C \Gamma_{11}\) contributions would come from the quasi-invariance of the WZ Lagrangian, while \(C \Gamma_{11}\) would be the result of the contribution of the \(A(\xi)\) field to the Noether current \(38\) see also Ref. [47]). This follows easily from the appropriate definition of the conserved Noether currents and charges (see, e.g., Ref. [26]) which include an additional piece when the Lagrangian is quasi-invariant, a common feature of the conventional actions for \(p\)-branes [12]. In the present D-branes case, there is an additional contribution due to the world-volume field \(A(\xi)\) since its transformation properties, \(\delta A = \Delta\), are postulated to compensate for those of the composite object \(B\), \(\delta B = d\Delta\), so that \(\mathcal{F} = dA - B\) is invariant. As a result, the supersymmetry transformations do not close on \(A\), and this produces an additional term by a mechanism similar to the one in the standard quasi-invariance case.

These modifications become evident in our context, i.e. by formulating the action on the extended superspace. Let us consider the D2-brane Lagrangian with the quasi-invariant WZ term \(b = b(x^\mu, \theta^\alpha, \varphi_\mu, \varphi_\alpha)\). The conserved Noether currents then have to include the quasi-invariance piece. If we wrongly ignored this additional term, the (canonical formalism) algebra of the corresponding (non-conserved, non-Noether) charges would be the algebra of the symmetries \(x^\mu, \theta^\alpha, \varphi_\mu, \varphi_\alpha\) of the Lagrangian, i.e.

\[
\{Q_\alpha, Q_\beta\} = (C \Gamma^\mu)_{\alpha\beta} P_\mu + (C \Gamma_\mu \Gamma_{11})_{\alpha\beta} \hat{Z}^\mu.
\]

(103)

The algebra of the conserved Noether charges is not (103), however, because these must include the quasi-invariance contribution. We may find the correct algebra immediately by replacing the quasi-invariant WZ term \(b\) by \(\hat{b} = \hat{b}(x^\mu, \theta^\alpha, \varphi_\mu, \varphi_\alpha, \varphi_{\mu\nu}, \varphi_{\alpha\beta}, \varphi)\), which is manifestly invariant since the transformation properties of the additional variables \(\varphi_{\mu\nu}, \varphi_{\alpha\beta}, \varphi)\) remove the quasi-invariance of \(b\). By definition, the transformation properties of all the coordinates obviously close into the group law or algebra. Hence, it follows that the algebra of charges computed using the canonical formalism reproduces (102), and that the contributions to \(\hat{Z}^{\mu\nu}\) and \(\hat{Z}\) are entirely due to the WZ term \(\hat{b}\) (or to the quasi-invariance of \(b(x^\mu, \theta^\alpha, \varphi_\mu, \varphi_\alpha)\) if we used \(b\) instead).
8. Branes with higher order tensors: the case of the M5-brane

We shall now show that the previous analysis can be applied also to other extended objects that are neither ordinary \( p \)-branes nor D-branes. We shall consider here the case of the \( D = 11 \) M5-brane, which contains a world-volume two-form field \( A \) in the action (see Ref. [51]). The action in a flat bosonic background depends on \( A \) through \( H_s dA y C \), where \( C \) is a background three-form. We shall take as our starting point the case with \( C = 0 \) and with all other forms of rank higher than one in that action vanishing. We do not need to worry about the (generalized) self-duality condition for \( A \) on the world-volume, since this condition may arise as a field equation for an auxiliary field (see Refs. [51,52]). The supersymmetric action of the M5-brane is obtained in two steps. First, one substitutes \( H_s dA y C \) for \( dA y C \), where \( C \) is a form on ordinary flat superspace such that

\[
dC_s y C = C_{GP mP nP aP b},
\]

and the transformation properties of the world-volume field \( A \) are fixed so that \( H \) is invariant. Secondly, a WZ term is added to obtain \( k \) symmetry.

Let us now find the WZ term in our framework. It should be obtained from the FDA generated by the abstract invariant forms \( \Pi^a, \Pi^\mu, H \),

\[
d\Pi^a = 0, \quad d\Pi^\mu = \frac{1}{2}(C \Gamma^\mu)_{a\beta} \Pi^a \Pi^\beta, \quad dH = (C \Gamma^\mu)_{a\beta} \Pi^a \Pi^\beta \Pi^\alpha \Pi^\beta, \tag{105}
\]

and be given by a CE-non-trivial potential \( b \) of a closed form \( h(\Pi^a, \Pi^\mu, H) \). Thus, we have to solve the problem of finding non-trivial \( (p + 2) \)-cocycles of the FDA (105). We shall find that there is no solution unless \( p = 5 \).

A general \( (p + 2) \)-form on (105) can be written as

\[
h = h^{(p + 2)} + h^{(p - 1)}H \tag{106}
\]

there are no further powers of \( H \) since \( H^2 \equiv H \wedge H = 0 \). The closure of \( h \) gives

\[
dh^{(p + 2)} + dh^{(p - 1)}H - (-1)^p h^{(p - 1)}(C \Gamma^\mu)_{a\beta} \Pi^a \Pi^\beta \Pi^\alpha = 0, \tag{107}
\]

which is equivalent to

\[
dh^{(p - 1)} = 0, \tag{108}
\]

\[
dh^{(p - 1)} = (-1)^p h^{(p - 1)}(C \Gamma^\mu)_{a\beta} \Pi^a \Pi^\beta \Pi^\alpha \tag{109}
\]

Now, since \( [h] = L^{p + 1} \) and \( [H] = L^3 \),

\[
h^{(p + 2)} = d^{(p + 2)}(C \Gamma_{\mu_1 \ldots \mu_p})_{a\beta} \Pi^{\mu_1} \ldots \Pi^{\mu_p} \Pi^a \Pi^\beta, \tag{10a}
\]

\[
h^{(p - 1)} = d^{(p - 1)}(C \Gamma_{\mu_1 \ldots \mu_{p - 1}})_{a\beta} \Pi^{\mu_1} \ldots \Pi^{\mu_{p - 1}} \Pi^a \Pi^\beta, \tag{10b}
\]

for some constants \( d^{(p + 2)} \) and \( d^{(p - 1)} \). The first equation in (108) requires \( d^{(p - 1)} = 0 \) unless \( p - 3 = 2 \), in which case \( d^{(p - 1)} \) is arbitrary due to the identity \( (C \Gamma^\mu)_{a\beta}(C \Gamma^\nu)_{\gamma\delta \nu} = 0 \), valid in \( D = 4, 5, 7, 11 \). If \( p \neq 5 \), \( d^{(p - 1)} = 0 \) and \( h^{(p - 1)} = 0 \), and the second equation of (108) gives \( dh^{(p + 2)} = 0 \), which again implies \( d^{(p + 2)} = 0 \).
unless \( p = 2 \). But if \( p \neq 2 \), we have \( h = h^{(2 + 2)} \alpha (C_{\mu\nu})_{\alpha\beta} \Pi^\alpha \Pi^\beta = dh \), in which case \( h \) is the differential of a LI form and hence CE-trivial. Thus we are just left with the case \( p = 5 \), \( d^{(5 - 1)} \) arbitrary. Inserting (109) in (108) gives, factoring out the \( \Pi^\alpha \)'s and \( \Pi^\alpha \)'s,
\[
\frac{2}{5} d^{(5 + 2)} (C_{\mu}^{\alpha})_{\alpha\beta} (C_{\mu\nu})_{\beta\gamma} + d^{(5 - 1)} (C_{\mu\nu})_{\alpha\beta} (C_{\rho\sigma})_{\gamma\delta} \delta_{\sigma}^{\beta} = 0.
\]
(110)
The second identity in (B.1) gives
\[
\frac{2}{7} d^{(7 - 1)} (C_{\mu\nu})_{\alpha\beta} \Pi^\alpha \Pi^\beta = \frac{2}{15} (C_{\mu\nu})_{\alpha\beta} \Pi^\alpha \Pi^\alpha \Pi^\beta \Pi^\beta \Pi^\alpha \Pi^\beta
\]
(111)
is not CE-exact, as may be seen by an argument analogous to that used in the IIA D-branes case: a LI potential form \( \tilde{b} \) would have to be a scalar six-form depending on \( \Pi^\alpha \), \( \Pi^\alpha \) and \( H \) with dimensions \( I^6 \), which does not exist.

It is possible to see, however, that a LI expression for \( H \) exists on the appropriate extended superspace. Since \( H \) is a three-form, it has formally the same properties as the invariant WZ term \( \tilde{b} \) of the M2-brane, the extended superspace of which is the one corresponding to the Lie FDA obtained by the methods of Section 3. Eqs. (3), (18), (21) and the first of (22) with \( (a_s, a_0, a_1, a_2) = (\frac{1}{2}, \frac{1}{2}, 1, - \frac{1}{2}) \) give, respectively,
\[
d\Pi^\alpha = 0,
\]
d\Pi = \frac{1}{2} (C_{\mu}^{\alpha})_{\alpha\beta} \Pi^\alpha \Pi^\beta,
\]
d\Pi = -\frac{1}{2} (C_{\mu}^{\alpha})_{\alpha\beta} \Pi^\alpha \Pi^\beta - \frac{1}{2} (C_{\mu}^{\alpha})_{\alpha\beta} \Pi^\alpha \Pi^\beta + \frac{1}{2} (C_{\mu}^{\alpha})_{\alpha\beta} \Pi^\alpha \Pi^\beta
\]
(112)
i.e. the dual of (61). Using again (73) we may then write
\[
H = \frac{2}{7} \Pi^\alpha \Pi^\alpha \Pi^\alpha + \frac{2}{7} \Pi^\alpha \Pi^\alpha \Pi^\alpha - \frac{2}{7} \Pi^\alpha \Pi^\alpha \Pi^\alpha.
\]
(113)

We might now go on and show that there exists a LI \( \tilde{b} \) such that \( h = d\tilde{b} \) on a suitably extended superspace; we shall omit its expression [19] since it is not needed below. What we wish to show is that now we may use (113) to replace the world-volume two-form \( A(\xi) \) by the pull-back of the two-form \( A \) on extended superspace given by
\[
A = \frac{2}{7} \varphi_{\alpha\beta} d\sigma d\theta^\alpha d\theta^\beta
\]
(114)
Again, this expression may also be used to find the gauge transformation \( \delta A(\xi) = d\lambda(\xi) \). This is achieved by the one-form on superspace \( \lambda = \lambda_\mu dx^\mu + \lambda_\alpha d\theta^\alpha \), \( \phi^* (\lambda) = \lambda(\xi) \). Then, if
\[
\delta \varphi_{\alpha\beta} = \frac{1}{2} \partial_\mu \lambda_\beta \mid \partial_\mu \lambda_\beta \mid,
\]
\[
\delta \varphi_{\alpha\beta} = \frac{1}{2} \partial_\mu \lambda_\beta \mid \partial_\mu \lambda_\beta \mid + \frac{1}{2} \partial_\alpha \lambda_\beta \mid (C_{\mu}^{\alpha})_{\alpha\beta} \theta^\beta,
\]
\[
\delta \varphi_{\alpha\beta} = \frac{1}{2} \partial_\mu \lambda_\beta \mid \partial_\mu \lambda_\beta \mid + \frac{1}{2} \partial_\alpha \lambda_\beta \mid (C_{\mu}^{\alpha})_{\alpha\beta} \theta^\beta
\]
(115)
one obtains \( \delta \phi^* (\lambda) = d\lambda(\xi) \).
As in the previous D-brane case, the EL equations derived from the action \( I[\phi^\mu, \theta^a, A_{ij}] \),

\[
\frac{\delta I}{\delta \phi^\mu} = 0, \quad \frac{\delta I}{\delta \theta^a} = 0, \quad \frac{\delta I}{\delta A_{ij}} = 0,
\]  

are equivalent to the ones corresponding to the new action in which \( A_{ij} \) is the pull-back of (114). Indeed, the equation for \( \phi_{\alpha \beta} \) gives

\[
\frac{\delta I}{\delta A_{ij}} \left( -\frac{1}{2} \partial_x \phi_{\alpha \beta} \partial_x \phi_{\alpha \beta} + \frac{1}{m} (C \Gamma^\mu)_{\alpha \beta} \partial_x \phi_{\alpha \beta} \partial_x \phi_{\alpha \beta} + \frac{1}{m} (C \Gamma^\mu)_{\alpha \beta} \delta \phi_{\alpha \beta} \delta \phi_{\alpha \beta} \right) = 0,
\]

(117)
gives

\[
\frac{\delta I}{\delta A_{ij}} \partial_x \phi_{\alpha \beta} = 0 \quad \text{and so on. Therefore one obtains}
\]

\[
\int d\xi^{\mu+1} \frac{\delta I}{\delta A_{ij}(\xi')} \frac{\delta A_{ij}(\xi)}{\delta \phi^\mu(\xi)} + \frac{\delta I}{\delta A_{ij}(\xi')} + \frac{\delta I}{\delta \phi^\mu(\xi)} = 0, \quad \frac{\delta I}{\delta A_{ij}} \partial_x \phi_{\alpha \beta} = 0, \quad \frac{\delta I}{\delta A_{ij}} \partial_x \phi_{\alpha \beta} = 0,
\]

(118)
The second equation implies \( \frac{\delta I}{\delta A_{ij}} \partial_x \phi_{\alpha \beta} = 0 \) for all \( \mu \) if one wants to avoid the possibility of one dimension of the object collapsing. This in turn implies \( \frac{\delta I}{\delta A_{ij}} = 0 \) for the same reason, and inserting this equation into (118) gives (116).

9. Conclusions

We have provided in this paper a unified approach to the study of various \( p \)-branes by defining them on suitably extended superspaces. All of these are supergroup manifolds, extensions of the basic odd abelian groups \( sT_{\mathfrak{g}} \) determined by the spinors of the specific theory considered. The extension algorithms in Sections 2.2 and 3 show how they depend, when they do, on specific identities for \( \Gamma \)-matrices. The central extensions do not need any \( \Gamma \)-identities, but the non-central ones require the identities (20), precisely the ones needed to define the WZ terms of the old branescan. The centrally extended superspaces are associated with (topological) charges, but the introduction of manifestly supersymmetric WZ terms requires the addition of non-central variables, already for the branes of the old branescan. When the procedure is applied to \( Dp \)-branes, it is seen that all the fields in their action may also be defined by pullbacks of entities on the previously introduced superspaces. In the language of FDA’s, our results show that all the FDA’s involved in the formulation of the \( p \)-branes considered here become \( \text{Lie} \) FDA’s on suitably extended superspaces. We conjecture, in view of the previous discussion, that this is the case in general and that there exists an extended superspace definition for all fields appearing in the action of the various \( p \)-branes. In other words, there exists a kind of field/extended superspace democracy by which all
brane world-volume fields are pullbacks from some target superspace $\Sigma$. The appropriate $\Sigma$ of the theory is given by an extension of a certain sTr$_p$ and, using $\Sigma$, the action can be defined in a manifestly invariant form. In fact, in this field/extended superspace democracy context, the invariance properties seem to characterize essentially the superbrane actions. It should not come then as a surprise that $\kappa$-symmetric actions may also be introduced for $Dp$-branes, as in [8] for D-branes with rigid IIA and IIB superPoincaré symmetry. As is the case for ordinary $p$-branes, $\kappa$-symmetry is achieved when the relative coefficient of the kinetic and WZ-like part is such that the Bogomol'nyi bound is saturated.

Our extensions provide at the same time a connection between the CE cocycles and the mechanism of partial breaking of supersymmetry. The CE $(p+2)$-cocycles lead to (extended) loop-type or world-volume current algebras (see, e.g., Refs. [12,15,53–55]) and the two-cocycle to the corresponding algebra of charges defining the extended superspace algebra. The new variables in the extended superspaces are also essential to define (invariant) actions. They may also be relevant in the problem of quantisation, the formulation of dualities (see Section 2.3.1) and in the formulation of the additional gauge freedom hidden in the definition of some superbrane fields, the world-volume definition of which reflects an election of gauge. We suspect that the mathematical existence of the extensions considered here has a deeper meaning beyond the aspects discussed in this paper.

Note added

After completion of this paper an article [56] has appeared, where an approach similar to that in Section 6.2 for the field $A$ is given for the IIB D-brane case.

Acknowledgements

C.C. wishes to thank the Spanish Ministry of Education and Culture for a post-doctoral fellowship and J.M.I acknowledges a grant from the Junta de Castilla y León. J.C.P.B. thanks the CSIC and the Ministerio de Educación for an FPI grant. Finally, the authors wish to thank Paul Townsend for helpful discussions.

Appendix A. Non-central extensions

We give here some details of the derivation of (22). After introducing $P_{\mu_1\ldots\mu_{p-2}\alpha_1}$ satisfying (21), we look for non-trivial CE 2-cocycles with external indices $(\mu_1\ldots\mu_{p-2}\alpha_1)$. There are four available LI two-forms with these indices,

$$\rho^{(1)} = (G^r)_{a_1,a_2} P^{r},$$

$$\rho^{(2)} = (G^r)_{a_1,a_2} P_{\nu_1\ldots\nu_{p-2} \mu}^{r},$$

$$\rho^{(3)} = (G^r)_{a_1,a_2} P_{\nu_1\ldots\nu_{p-2} \beta}^{r},$$

$$\rho^{(4)} = (G^r)_{a_1,a_2} P_{\nu_1\ldots\nu_{p-2} \beta}^{r}. \quad (A.1)$$
none of which is closed. Looking for a linear combination $\rho \equiv \rho^{(1)} + \lambda_2 \rho^{(2)} + \lambda_3 \rho^{(3)} + \lambda_4 \rho^{(4)}$ that is closed, we compute (making use of the MC equations for the available $\Pi^\gamma$’s)

$$
\begin{align*}
\rho &= \left\{ 2a_3(C \Gamma_{\mu \nu \rho \ldots \mu_{p-2}})_{a_1}a_2(C \Gamma^\mu)_{a_1}a_2(C \Gamma_{\mu \nu \rho \ldots \mu_{p-2}})_{\gamma \delta} + \lambda_2 a_0(C \Gamma^\mu)_{a_1}a_2(C \Gamma_{\mu \nu \rho \ldots \mu_{p-2}})_{\gamma \delta} \\
&\quad + \lambda_3 a_1(C \Gamma^\nu)_{a_1}a_2(C \Gamma_{\mu \nu \rho \ldots \mu_{p-2}})_{\gamma \delta} - \lambda_4 a_1(C \Gamma^\mu)_{a_1}a_2(C \Gamma_{\mu \nu \rho \ldots \mu_{p-2}})_{\gamma \delta} \right\} \Pi^\gamma \Pi^\delta \\
&\quad + \left\{ -\lambda_2 a_1(C \Gamma^\mu)_{a_1}a_2(C \Gamma^\nu)_{\gamma \delta} + \lambda_3 \frac{a_3 a_1}{a_0} (C \Gamma^\mu)_{a_1}a_2(C \Gamma^\mu)_{\gamma \delta} \\
&\quad + \lambda_4 \frac{a_3 a_1}{a_0} (C \Gamma^\nu)_{a_1}a_2(C \Gamma^\mu)_{\gamma \delta} \right\} \Pi_{\mu \nu \rho \ldots \mu_{p-2}} \Pi_\gamma \Pi_\delta.
\end{align*}
$$

(A.2)

Inside the first curly brackets above, one can combine the third term with the second, changing at the same time its sign the $\Gamma$’s are antisymmetric in the vector indices. In the fourth term, one can also symmetrise over $\gamma$, $\delta$ (since $\Pi_\gamma$ and $\Pi_\delta$ commute). Effecting explicitly this symmetrisation, as well as the indicated one by the primes over $\alpha_1$, $\alpha_2$, one gets four terms, which, together with the other two, give exactly the six permutations of $20$ the $\Gamma$’s are symmetric in the spinorial indices, so that the twenty-four permutations of $20$ reduce to six. The sum of all six terms will be zero (due to $20$) if their coefficients are equal – this gives the equations

$$
\begin{align*}
\lambda_3 &= 2a_3, \\
-\frac{1}{2}a_1 \lambda_4 &= 2a_4.
\end{align*}
$$

(A.3)

Inside the second curly brackets in (A.2), the last term is zero because of antisymmetry in $\mu$, $\nu$. The sum of the first two will be zero (for the same reason) if their coefficients are equal, i.e. if

$$
\begin{align*}
a_3 \lambda_2 + \frac{a_3 a_1}{a_0} \lambda_3 &= 0.
\end{align*}
$$

(A.4)

Solving the linear system of (A.3), (A.4) one gets

$$
\begin{align*}
\lambda_2 &= \frac{a_3}{a_0}, \\
\lambda_3 &= -\frac{a_2}{a_1}, \\
\lambda_4 &= -8 \frac{a_3}{a_1}.
\end{align*}
$$

(A.5)

which leads to the first of (22).

For the next extension, looking for LI two-forms with indices $(\mu_1 \ldots \mu_{p-2} \alpha_1 \alpha_2 \alpha_3)$ we find

$$
\begin{align*}
\rho^{(1)} &= (C \Gamma^\rho)_{a_1}a_2 \Pi_{\mu \nu \rho \ldots \mu_{p-2} a_1} \Pi^\rho, \\
\rho^{(2)} &= (C \Gamma^\rho)_{a_1}a_2 \Pi_{\mu \nu \rho \ldots \alpha_2 \alpha_3} \Pi^\rho, \\
\rho^{(3)} &= (C \Gamma^\rho)_{a_1}a_2 \Pi_{\mu \nu \rho \ldots \beta \alpha_3} \Pi^\rho.
\end{align*}
$$

(A.6)
none of which is closed (we use, for simplicity, the same symbols $\rho$, $\lambda$ as in the previous extension). For their linear combination $\rho \equiv \rho^{(1)} + \lambda_2 \rho^{(2)} + \lambda_3 \rho^{(3)}$ we compute

\[
d\rho = (C \Gamma^\nu) \alpha_i' \alpha_i \left( C \Gamma_{\lambda \rho \mu_1 \ldots \mu_{p-1}} \right) \beta_{\alpha_i'} \Pi^\alpha \Pi^\beta
\]

\[
+ \frac{a_2}{a_0} (C \Gamma^\nu) \alpha_i' \alpha_i \Pi_{\lambda \rho \mu_1 \ldots \mu_{p-1}} \Pi^\beta \right) \Pi^\rho
\]

\[- a_2 (C \Gamma^\nu) \alpha_i' \alpha_i (C \Gamma^\nu)^\gamma \Pi_{\lambda \rho \mu_1 \ldots \mu_{p-1} \gamma} \Pi^\beta
\]

\[
+ \lambda_2 a_2 (C \Gamma^\nu) \alpha_i' \beta \left( C \Gamma_{\lambda \rho \mu_1 \ldots \mu_{p-1}} \right) \alpha_i' \alpha_i \Pi^\alpha \Pi^\beta
\]

\[
+ \frac{a_3}{a_0} (C \Gamma^\nu) \alpha_i' \alpha_i \Pi_{\lambda \rho \mu_1 \ldots \mu_{p-1}} \Pi^\beta - \frac{a_1}{a_1} (C \Gamma^\nu) \alpha_i' \alpha_i \Pi_{\lambda \rho \mu_1 \ldots \mu_{p-1} \gamma} \Pi^\gamma
\]

\[-8 \frac{a_1}{a_1} (C \Gamma^\nu) \alpha_i' \gamma \Pi_{\lambda \rho \mu_1 \ldots \mu_{p-1} \gamma} \Pi^\gamma \right) \Pi^\beta
\]

\[
+ \lambda_3 a_2 (C \Gamma^\nu) \alpha_i' \beta \left( C \Gamma_{\lambda \rho \mu_1 \ldots \mu_{p-1}} \right) \alpha_i' \alpha_i \Pi^\alpha \Pi^\beta
\]

\[
+ \frac{a_3}{a_0} (C \Gamma^\nu) \beta_{\alpha_i'} \Pi_{\lambda \rho \mu_1 \ldots \mu_{p-1} \gamma} \Pi^\gamma
\]

\[-8 \frac{a_1}{a_1} (C \Gamma^\nu) \beta_{\alpha_i'} \Pi_{\lambda \rho \mu_1 \ldots \mu_{p-1} \gamma} \Pi^\gamma \right) \Pi^\beta
\]

(A.7)

(the barred indices in the last term denote a second symmetrisation, besides the one over the primed indices). There is a novelty here compared with the previous extension: there are four different types of terms in the $\Pi$’s, the coefficients of which must separately vanish, giving rise to four linear equations for the two unknowns $\lambda_2$, $\lambda_3$ (care must be taken of the fact that when the second symmetrisation in the last term above is effected, corresponding to the barred indices, one obtains contributions to two different types of terms in the $\Pi$’s). Making use of (20) and of the symmetry properties of the $\Gamma$’s, as in the previous extension, one arrives at the (overdetermined) linear system

\[
\lambda_2 - \lambda_3 = \frac{a_1}{a_2}, \quad 4 \frac{a_1 a_2}{a_1} \lambda_3 = a_4, \quad \lambda_2 - 5 \lambda_3 = 0 \quad (A.8)
\]

(the first equation appears twice) which nevertheless admits the solution

\[
\lambda_2 = \frac{5a_1}{4a_2}, \quad \lambda_3 = \frac{a_1}{4a_2} \quad (A.9)
\]

leading to the second of (22). The last of (22), as well as (23), are proved similarly.
Appendix B. \( D = 10 \) \( \Gamma \)-matrix identities

We prove here the \( \Gamma \)-identities needed in Section 6.1\(^{16} \). The first two identities in (85) follow by dimensional reduction from the known \( D = 11 \) relations

\[
(C \Gamma_{\tilde{\mu}_1 \ldots \tilde{\mu}_2})_{\tilde{\alpha} \tilde{\beta}} (C \Gamma_{\tilde{\mu}_1 \ldots \tilde{\mu}_2})_{\tilde{\alpha} \tilde{\beta}} = 0,
\]

\[
(C \Gamma_{\tilde{\mu}_1 \ldots \tilde{\mu}_5})_{\tilde{\alpha} \tilde{\beta}} (C \Gamma_{\tilde{\mu}_1 \ldots \tilde{\mu}_5})_{\tilde{\alpha} \tilde{\beta}} - 3(C \Gamma_{\tilde{\mu}_1 \tilde{\mu}_2 \tilde{\mu}_3})_{\tilde{\alpha} \tilde{\beta}} (C \Gamma_{\tilde{\mu}_1 \tilde{\mu}_2 \tilde{\mu}_3})_{\tilde{\alpha} \tilde{\beta}} = 0, \tag{B.1}
\]

where the tilded indices \( \tilde{\mu} = 0, 1, \ldots, 10 \).

The third identity can be proved as follows. First, using that \( \Gamma_{\mu_1 \ldots \mu_5} = 5 \Gamma_{\mu_1 \ldots \mu_5} \eta_{\mu_1 \mu_6} \) and the fact that \( \Gamma_{\mu_1 \ldots \mu_5} \Gamma_{\mu_1 \ldots \mu_5} \) is antisymmetric.

Finally, the fourth equation in (85) may be shown to be equivalent to the second. Indeed, by multiplying the fourth identity by \( \epsilon_{\mu_1 \ldots \mu_5} \eta_{\mu_1 \mu_6} \) and using that

\[
\Gamma_{\mu_1 \ldots \mu_5} \Gamma_{\mu_1 \ldots \mu_5} \propto \frac{1}{(10-q)^!} \epsilon_{\mu_1 \ldots \mu_5} \Gamma_{\mu_1 \ldots \mu_5} \Gamma_{\mu_1 \ldots \mu_5},
\]

one obtains

\[
\frac{7!3!}{2} (C \Gamma_{\nu_1})_{\nu_1 \nu_1} (C \Gamma_{\nu_2 \nu_1})_{\nu_1 \nu_1} + \frac{6!4!7!}{4!} (C \Gamma_{\mu_1 \mu_2 \mu_3 \nu_1} \Gamma_{\mu_1 \mu_1})_{\nu_1 \nu_1} (C \Gamma_{\mu_1 \mu_1} \Gamma_{\mu_1 \mu_1})_{\nu_1 \nu_1} = 0, \tag{B.5}
\]

which is equivalent to the second equation in (B.1) due to the fact that \( i \Gamma_{\mu} \Gamma_{\mu} \) realize the same Clifford algebra as \( \Gamma_{\mu} \).

References

\(^{16}\) In the search for further possible \( \Gamma \)-identities the results in [57] may be useful.
