Shape Coexistence: the	basics				

What Shape Coexistence (SC) is?

It appears in quantum systems where eigenstates with very different density distribution coexist. Therefore, the existence of a geometric interpretation is implicit.

Quadrupole shape invariants

$$\begin{array}{lll} q_{2,i} &=& \sqrt{5} \langle 0_i^+ | [\hat{Q} \times \hat{Q}]^{(0)} | 0_i^+ \rangle, \\ q_{3,i} &=& -\sqrt{\frac{35}{2}} \langle 0_i^+ [\hat{Q} \times \hat{Q} \times \hat{Q}]^{(0)} | 0_i^+ \rangle, \\ q_2 &=& q^2, q_3 = q^3 \cos 3 \, \delta. \end{array}$$

Shape Coexistence: the	basics				

Shell model. Where to be used

- For nuclei near to closed shells, either for neutrons or for protons, it can be energetically favorable to have excitations of 2p-2h, 4p-4h ... crossing the energy gap.
- The np-nh excitations have a lower excitation energy than expected due to the correlation energy: pairing and deformed correlations.
- Restricted to light and medium-heavy nuclei, at present.

In heavy nuclei the huge model space imposes some kind of truncation: symmetry dictated truncation.

A symmetry guided approximation: the IBM

Nucleons couple preferably in pairs with angular momentum either equal to 0 (S) or equal to 2 (D). Those pairs are then described by means of bosons: s and d.

$$s^{\dagger}, d_m^{\dagger}(m = 0, \pm 1, \pm 2) \ s, d_m(m = 0, \pm 1, \pm 2)$$

with

$$\begin{split} & [\gamma_{lm},\gamma^{\dagger}_{l'm'}] = \delta_{ll'}\delta_{mm'}, \\ & [\gamma^{\dagger}_{lm},\gamma^{\dagger}_{l'm'}] = 0, [\gamma_{lm},\gamma_{l'm'}] = 0 \end{split}$$

Simplified Hamiltonian

$$\hat{H}_{ECQF} = \varepsilon \hat{n}_d + \kappa \hat{Q} \cdot \hat{Q} + \kappa' \hat{L} \cdot \hat{L}$$

Model based on a u(6) spectrum generator algebra. It is especially suited for medium and heavy-mass nuclei. The number of bosons, N, corresponds the number of nucleons pairs, regardeless its proton, neutron, particle or hole nature.

A different Hamiltonian, \hat{H}_{ECQF}^{N} and \hat{H}_{ECQF}^{N+2} , acts on the regular [N] and intruder [N+2] sectors, separately. The offset Δ^{N+2} and the mixing interaction $\hat{V}_{mix}^{N,N+2}$ should be provided.

Quantum Phase Transit	tions				

What a Quantum Phase Transition (QPT) is?

A QPT appears when the ground state a quantum system experiences a sudden change in its structure (order parameter) when a parameter that affects the Hamiltonian (control parameter) slightly changes around its critical value. This transitions are assumed to occurs at zero temperature.

$$\hat{H}=(1-\xi)\hat{H}_1+\xi\hat{H}_2$$

QPT vs SC	Key indicators	Sr-Zr	Mo-Ru	Odd-even	Discussion

What a Quantum Phase Transition (QPT) is?

A QPT appears when the ground state a quantum system experiences a sudden change in its structure (order parameter) when a parameter that affects the Hamiltonian (control parameter) slightly changes around its critical value. This transitions are assumed to occurs at zero temperature.

 $\hat{H} = (1-\xi)\hat{H}_1 + \xi\hat{H}_2$

Pb and Sn regions are ideal regions to study the importance of Shape Coexistence (SC). Sm region is the paradigm of Quantum Phase Transition (QPT) region. Zr region seems to be the ideal region to study the interplay between SC and QPT.

Quantum Phase Tra	ansition indicators				

Quantum Phase Transition indicators in the rare-earth region: Type I

Two-neutron separation energy. Why?

 S_{2n} is connected with the first derivative of the binding energy. Its discontinuity is a hint for the onset a first order QPT.

$E(4_1^+)/E(2_1^+)$

 $E(4_1^+)/E(2_1^+)$ can be used as an order parameter and, therefore, it is a key observable to find where a QPT develops.

Conclusions or rather open questions

- Lead region clearly shows up the onset of shape coexistence. Large mixing and relative energies hinder the onset of a Quantum Phase Transition.
- Rare-earth region is the most clear cut example of *critical region*, but without clear influence of shape coexistence, although the SU3-proxy symmetry supports the presence of neutron particle-hole excitations (Bonatsos et al).
- Are both descriptions compatible? The answer is in Zr region: type I and type II QPT introduced by Gavrielov, Leviatan and lachello
- Can a Quantum Phase Transition be described in terms of the onset of intruder configurations?
- How things change in odd-even nuclei?
- Is shape coexistence always present *before* a Quantum Phase Transition sets in, or are they fully disconnected?

 - Lead region clearly shows up the onset of shape coexistence. Large mixing and relative energies hinder the onset of a Quantum Phase Transition.
 - Rare-earth region is the most clear cut example of *critical region*, but without clear influence of shape coexistence, although the SU3-proxy symmetry supports the presence of neutron particle-hole excitations (Bonatsos et al).
 - Are both descriptions compatible? The answer is in Zr region: type I and type II QPT introduced by Gavrielov, Leviatan and lachello
 - Can a Quantum Phase Transition be described in terms of the onset of intruder configurations?
 - How things change in odd-even nuclei?
 - Is shape coexistence always present *before* a Quantum Phase Transition sets in, or are they fully disconnected?

QPT vs SC	Key indicators	Sr-Zr	Mo-Ru	Odd-even	Discussion
